1 Introduction

1.1 Trial information

This is a phase 3b, 26-week, multicentre, multinational, partly double-blind, randomised, active controlled, treat-to-target, three-armed parallel trial with an 8-week run-in period comparing the efficacy and safety of fast-acting insulin aspart with NovoRapid[®], both in combination with insulin degludec in a basal-bolus regimen. The trial includes two blinded dosing arms - mealtime fast-acting insulin aspart and mealtime NovoRapid[®] and an open-label postmeal fast-acting insulin aspart dosing arm (Figure 1-1).

The total duration of the trial is approximately 40 weeks divided into the following periods:

An approximate 2-week screening period

An 8-week run-in period primarily for optimisation of the basal insulin and subject training

An 26-week treatment period

An 30-day follow-up period

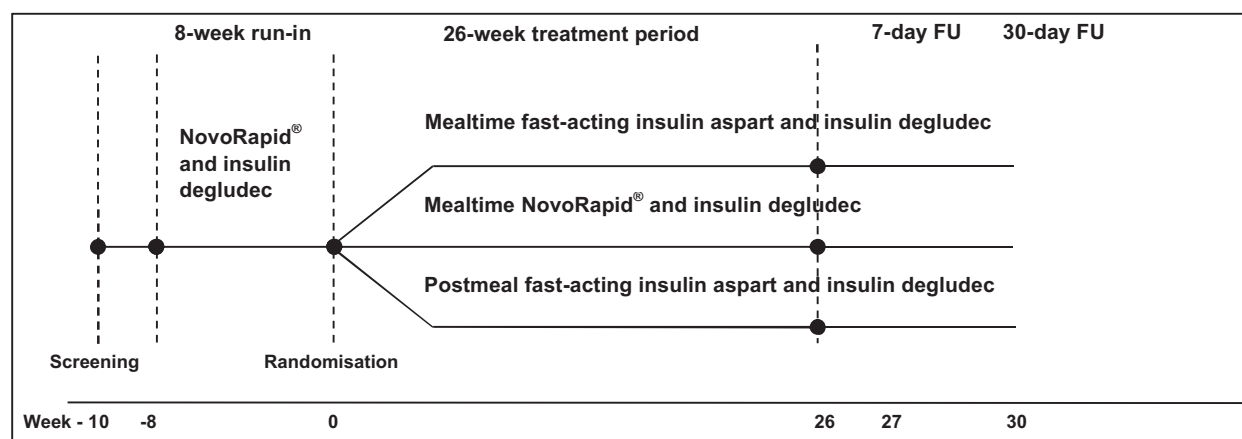

Figure 1-1 Trial design

The trial includes a screening period followed by weekly visits/phone contacts during the trial. At Visit 2 all eligible subjects will be enrolled in an 8-week run-in period and start treatment with NovoRapid[®] and insulin degludec. After the run-in period, subjects with an $HbA_{1c} \leq 9.5\%$ (80 mmol/mol) will be randomised (1:1:1) to mealtime NovoRapid[®] or to receive either mealtime fast-acting insulin aspart or postmeal fast-acting insulin aspart in addition to insulin degludec.

For further details see the trial protocol.

1.2 Scope of the statistical analysis plan

This SAP is based on the protocol Efficacy and Safety of Faster-acting Insulin Aspart compared to NovoRapid® both in combination with Insulin Degludec in Adults with Type 1 Diabetes, final version 1.0, Local Amendment no.1 version 1.0, Global Amendment no.2 version 1.0, and Local Amendment no.3 version 1.0. It contains a more detailed description for deriving and calculation of endpoints. Furthermore, it details changes to the statistical considerations presented in the protocol.

The changes to the statistical considerations proposed in this SAP and the reasons for the changes will be reported in the clinical trial report.

2 Statistical considerations

General considerations

In general, for endpoints evaluated as a change from baseline and/or where a baseline adjustment is made, baseline is defined as information collected at the randomisation visit (Visit 10). In case a measurement is not available at the randomisation visit, the most recent measurement prior to the randomisation visit will be used as baseline.

Two observation periods are defined, “in-trial” and “on-treatment”, and it will be specified which period each analysis will use.

- In-trial: the observation period from date of randomisation and until last trial-related subject-site contact. The in-trial observation period includes data collected after treatment discontinuation.
- On-treatment: the observation period from date of first dose of randomised NovoRapid®/fast-acting insulin aspart and no later than 7 days after the day of last dose of randomised NovoRapid®/fast-acting insulin aspart. The on-treatment observation period includes data collected up to and including 7 days after treatment discontinuation.

All efficacy endpoints will be summarised and analysed using the full analysis set (FAS), unless otherwise stated. Safety endpoints will be summarised using the safety analysis set (SAS) and analysed using the FAS.

Presentation of results from a statistical analysis will include the estimated mean treatment effects (LSMeans) for change from baseline, if applicable. Estimated mean treatment differences (or ratios) will be presented together with two-sided 95% confidence intervals for all endpoints analysed statistically.

For endpoints measured over time mean values will be plotted to explore the trajectory over time. For survival endpoints, e.g. drop-out pattern, Kaplan-Meier plots are presented for each treatment.

Data collected before randomisation will only be summarised descriptively.

Subjects that prematurely discontinue from treatment or withdraw from trial will attend end of treatment visit called Visit 36A. Data collected at these visits will be reallocated to the next scheduled visit where the given assessment is planned. As a general rule, all observed values from randomised subjects will be used in all statistical analyses, but in case two different values are associated to the same visit in time, the use of a given value will depend on the estimand of interest. For the primary estimand the reallocated on-treatment value will not be used and for the secondary estimand the reallocated on-treatment value will be used. The estimands will be defined in the next section.

Testing strategy and estimands

The primary objective, confirming the effect of treatment with mealtime fast-acting insulin aspart compared to NovoRapid[®] both in combination with insulin degludec in adults with type 1 diabetes, will be assessed by the change from baseline HbA_{1c} using a non-inferiority approach.

More specifically the upper limit of the 95% confidence interval (CI) should be compared to a non-inferiority margin of 0.4%. If it is below or equal to 0.4%, non-inferiority will be considered confirmed and effect demonstrated.

The trial also aims to compare treatment arms for a number of confirmatory secondary endpoints. The family-wise type I error rate will be controlled in the strong sense using a hierarchical (fixed sequence) testing procedure for the primary estimand. This is based on a priority ordering of the null-hypotheses, and testing them in this order using the two-sided 95% CI approach until a non-significant result appears. The effect is that rejection of the null hypothesis only will be confirmed for analyses where all previous null-hypotheses have been rejected in favour of fast-acting insulin aspart.

The steps in the hierarchical testing procedure are:

Step 1 (Primary analysis): HbA_{1c} non-inferiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid[®]

Step 2: HbA_{1c} non-inferiority of postmeal fast-acting insulin aspart versus mealtime NovoRapid[®]

Step 3: 1-hour postprandial glucose (PPG) increments superiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid[®]

Step 4: HbA_{1c} superiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid[®]

Step 5: 1,5-anhydroglucitol superiority of mealtime fast -acting insulin aspart versus mealtime NovoRapid®

Primary Estimand (de facto)

The primary estimand is defined as the treatment difference between subjects randomised to fast-acting insulin aspart and NovoRapid® both in combination with insulin degludec, in adults with type 1 diabetes assessed by change from baseline in HbA_{1c} 26 weeks after randomisation for all randomised subjects regardless of treatment discontinuation or use of ancillary therapies. This estimand is a de facto estimand addressing effectiveness.

The primary estimand assesses the expected glycaemic benefit a future population with type 1 diabetes can achieve if prescribed to fast-acting insulin aspart as compared to NovoRapid®. By not putting any restrictions on the treatment adherence, this estimand aims at a difference as close as possible to the one that can be expected in real-world clinical practice, provided that the treatment adherence and use of ancillary therapies reflect clinical practice. Thereby the primary estimand provides a treatment difference for clinicians concerning the glycaemic effect of fast-acting insulin aspart compared to NovoRapid® in the day to day life in individual subjects with type 1 diabetes in an adult population.

Secondary Estimand (de jure)

Unlike the primary estimand, a second estimand is defined as the treatment difference in change from baseline in HbA_{1c} 26 weeks after randomisation between fast-acting insulin aspart and NovoRapid® both in combination with insulin degludec in adult subjects with type 1 diabetes if subjects continue on-treatment until 26 weeks. This estimand is a de jure estimand, addressing efficacy.

As an alternative to the primary estimand, this estimand provides a more hypothetical treatment difference, but may also be the most sensitive for a non-inferiority comparison, since the intake of ancillary medication may equalize the treatment effect resulting in a difficult assessment if a difference is seen with respect to ancillary medication.

The two estimands described above define what needs to be estimated to evaluate treatment differences in change from baseline in HbA_{1c}. By replacing in these descriptions HbA_{1c} with a different endpoint, one obtains analogous primary and secondary estimands specific for this endpoint (similarly for any sensitivity analyses associated with the estimands). This will be done for the following endpoints:

- Change from baseline in 1-hour PPG increment 26 weeks after randomisation (meal test)
- Change from baseline in 1,5-anhydroglucitol 26 weeks after randomisation

2.1 Sample size calculation

The primary objective of this trial is to confirm the effect of treatment with mealtime fast-acting insulin aspart in combination with insulin degludec. This is done by showing that mealtime fast-acting insulin aspart is non-inferior to mealtime NovoRapid® both in combination with insulin degludec in terms of glucose lowering effect as assessed by mean change from baseline in HbA_{1c} 26 weeks after randomisation using a non-inferiority margin of 0.4% (absolute). The non-inferiority margin of 0.4% (absolute) was chosen as described in section protocol section 5.2.1. The statistical evaluation will be done as described in section 2.3.

The trial also aims to confirm the effect of treatment with mealtime fast-acting insulin aspart and postmeal fast-acting insulin aspart, for a number of secondary confirmatory endpoints using the hierarchical testing procedure as described in section 2. The sample size is determined to ensure a sufficient power for the first step (the primary objective: HbA_{1c} non-inferiority of mealtime fast-acting insulin aspart) and the second step (HbA_{1c} non-inferiority of postmeal fast-acting insulin aspart) in the hierarchical testing procedure.

In, previous trials where faster aspart has been investigated in similar designs, the completion rates have been high. Therefore it is expected that treatment discontinuation might be as low as 8% where trial discontinuation constitutes half of these.

Power for the non-inferiority steps are based on a t-statistic under the assumption of a one-sided test of size 2.5%. A zero mean treatment difference for the comparison between mealtime fast-acting insulin aspart and mealtime NovoRapid® is expected, and for the comparison of postmeal fast-acting insulin aspart and mealtime NovoRapid® a mean difference of 0.1% in favor of mealtime NovoRapid® is expected. As trials in this population where subjects discontinuing treatment are followed up are limited, a conservative estimate of the standard deviation (SD) in change from baseline in HbA_{1c} of 1.2% was chosen. The power calculation is done using 'proc power' in SAS 9.4. Please refer to Table 2-1 for assumption of the sample size calculation.

Table 2-1 Specifications assumed for sample size calculation

	Statistical test	Significance level	Analysis population	Non-inferiority margin	SD	Mean difference	Randomisation scheme
Step 1	2-group t-test	One-sided 2.5%	FAS	0.4% (absolute)	1.2	0.0	1:1
Step 2	2-group t-test	One-sided 2.5%	FAS	0.4% (absolute)	1.2	0.1	1:1

Table 2-2 Sensitivity of sample size to power in each step

		Primary (Step 1)			Step 2		
N total	N per arm	Mean	SD	Power (step	Mean	SD	Power (step 2)
FAS	FAS	Diff		1) (%)	Diff		(%)
813	271	0	1.2	97.2	0.1	1.2	82.8
999	333	0	1.2	99.0	0.1	1.2	89.6
1176	392	0	1.2	99.7	0.1	1.2	93.8

From the [Table 2-2](#) it can be seen that, based on the previously defined assumptions, a total of 333 subjects per arm give 99.0% power to conclude HbA_{1c} non-inferiority in the first step. This sample size gives 89.6% marginal power to conclude HbA_{1c} non-inferiority in the second step which is considered sufficient.

2.2 Definition of analysis sets

The following analysis sets are defined in accordance with the ICH-E9 guideline¹.

- FAS includes all randomised subjects. In exceptional cases, randomised subjects may be excluded from the FAS. In such cases, the reason for exclusion will be justified and documented. Subjects in the FAS will contribute to the evaluation “as randomised”.
- Per Protocol (PP) Analysis Set includes all subjects in the full analysis set, excluding subjects who:
 - have violated any inclusion criteria
 - have fulfilled any exclusion criteria

Subjects in the PP analysis set will contribute to the evaluation “as treated”.

- SAS includes all subjects receiving at least one dose of the investigational product or its comparator. Subjects in the SAS will contribute to the evaluation “as treated”.

Randomised subjects who are lost to follow up, and where no information on exposure to the investigational product or its comparator is available after randomisation, will be handled as unexposed.

Before data are released for statistical analysis, a blinded review of all data will take place to identify protocol deviations that may potentially affect the results. Furthermore, extreme values and outliers will be identified by the statistician during programming and data review, according to ICH-E9¹. This will be performed using a fake randomisation.

The subjects or observations to be excluded, and the reasons for their exclusion must be documented and signed by those responsible before database lock. The subjects and observations excluded from analysis sets, and the reason for this, will be described in the clinical trial report.

2.3 Primary endpoint

The primary endpoint is change from baseline in HbA_{1c} 26 weeks after randomisation.

Primary analysis:

- 1) The primary estimand will be addressed by the below primary analysis based on all subjects included in FAS and using the in-trial observation period. Note that if subjects withdraw consent to contribute additional information or are completely lost to follow-up, missing data will still occur. The primary analysis will be implemented as a statistical model using multiple imputation where the subjects without HbA_{1c} measurements at scheduled visits will have their change from baseline HbA_{1c} value(s) imputed from the available information from the treatment the subject has been randomised to. Note that this resembles in essence a mixed model of repeated measurements analysis, but subjects without post-randomisation measurements contribute to the analysis, as the missing values will be imputed. The analysis will be implemented as follows:
 - In the first step, intermittent missing values are imputed using a Markov Chain Monte Carlo (MCMC) method, in order to obtain a monotone missing data pattern. This imputation is done for each group separately and 100 copies of the dataset will be generated.
 - In the second step, for each of the 100 copies of the dataset, an analysis of variance model with region and bolus adjusting method at randomisation (principles of flexible dosing based on the carbohydrate content of the meal or using bolus dosing algorithms) as a factors, and baseline HbA_{1c} as a covariate is fitted to the change in HbA_{1c} from baseline to week 4 for each treatment group separately. The estimated parameters, and their variances, from these models are used to impute missing values at week 4 for subjects in each treatment group, based on region, bolus adjusting method and baseline HbA_{1c}.
 - In the third step, for each of the 100 copies of the dataset, missing values at week 8 are imputed in the same way as for week 4. The imputations are based on an analysis of variance model with region and bolus adjusting method as a factors and baseline HbA_{1c} and change from baseline in HbA_{1c} at week 4 as covariates.
 - This stepwise procedure is then repeated sequentially for week 12, 16, 20, 24 and 26

- For each of the complete data sets, the change from baseline to week 26 is analysed using an analysis of variance model with treatment, region, and bolus adjusting method as factors, and baseline HbA_{1c} as a covariate.
- The estimates and standard deviations for the 100 data sets are pooled using Rubin's formula:

$$m_{MI} = \frac{1}{100} \sum_{i=1}^{100} m_i, \quad SD_{MI} = \sqrt{\frac{1}{100} \sum_{i=1}^{100} SD_i^2 + \left(1 + \frac{1}{100}\right) \left(\frac{1}{100 - 1}\right) \sum_{i=1}^{100} (m_i - m_{MI})^2},$$

where m_i and SD_i are the estimated means and standard deviations for the 100 copies of the dataset, and m_{MI} and SD_{MI} are the pooled estimates.

- From m_{MI} and SD_{MI} , the 95% CI for the treatment differences is calculated (see also the second step in the hierarchy).

Non-inferiority of mealtime fast-acting insulin aspart will be considered confirmed if the upper boundary of the two-sided 95% CI is below or equal to 0.4% or equivalent if the p-value for the one-sided test of

$$H_0: D > 0.4\% \text{ against } H_A: D \leq 0.4\%$$

is less than or equal to 2.5%, where D is the mean treatment difference (mealtime fast-acting insulin aspart minus mealtime NovoRapid®).

Note that as the anticipated number of subjects discontinuing treatment, but not trial is low, imputations based on such subjects will not be feasible.

Provided that the hierarchical testing allows, the evaluation of HbA_{1c} non-inferiority of postmeal fast-acting insulin aspart and HbA_{1c} superiority of mealtime fast-acting insulin aspart (steps 2 and 4 in the hierarchical testing procedure) will be based on the same statistical model as the primary analysis in 1), and supplemented with the associated sensitivity analyses (analysis 3b and 3c below).

Furthermore similar sensitivity analyses can be made to further investigate the remaining confirmatory hypothesis.

Sensitivity analyses for the primary analysis addressing the primary estimand

- 2) First, the primary analysis in 1) will be repeated, but excluding all factors except treatment from the multiple imputation and analysis of variance models while still including baseline

HbA1c as a covariate. This analysis will explore the influence of the different factors. The analysis will use the in-trial observation period.

- 3) The primary analysis approach chosen for this trial relies on the assumption that missing data is missing at random (MAR). This assumption implies that the HbA1c for subjects leaving the trial, after their withdrawal, develops in a similar way as the HbA1c for similar subjects that remain in the trial (not necessarily on treatment) and had similar development of HbA1c before withdrawal. The MAR assumption may be questionable for subjects withdrawing at own will. Therefore the statistical model using multiple imputation will be repeated with the following alterations:
- Imputation will be done from the treatment arm that the subject was randomised to and a value of 0.4% (the non-inferiority margin) is added to the change in HbA_{1c} at 26 weeks for subjects, on either of the fast-acting insulin aspart arms, with an imputed value at week 26². The analysis will use the in-trial observation period.
 - Missing values at week 26 will be imputed from the comparator arm (NovoRapid[®]). This will serve as a sensitivity analysis for the superiority analysis. It does not rely on the MAR assumption, but assumes that subjects on fast-acting insulin aspart without a measurement at week 26 switch to NovoRapid[®]. The imputation will be done such that the treatment effect diminishes gradually (conditional imputation). The analysis will use the in-trial observation period.
 - Missing values at week 26 will be imputed from the comparator arm (NovoRapid[®]). This will serve as a supplementary sensitivity analysis for the superiority analysis. It does not rely on the MAR assumption, but assuming that subjects on fast-acting insulin aspart without a measurement at week 26 switch to NovoRapid[®]. The imputation will be done such that the treatment effect diminishes immediately (unconditional imputation). The analysis will use the in-trial observation period.

Analyses addressing the secondary estimand

- The secondary estimand will be addressed using the same statistical model using multiple imputations as the primary analysis in 1) except using the on-treatment observation period.
- A tipping point analysis based on a statistical model using multiple imputations similar to 1), using the on-treatment observation period, will be made. In this analysis, observations for subjects without a measurement are imputed based on the treatment arm they were randomised to and subjects without a measurement in the fast-acting insulin aspart group under investigation are given a penalty. Specifically, for treatment differences involving the mealtime fast-acting insulin aspart group, only subjects in this group are given a penalty, and vice versa for treatment differences involving the postmeal fast-acting insulin aspart group. This is done to investigate the robustness of the conclusion in the primary analysis with respect to the MAR

assumption and mimics a scenario where the HbA_{1c} of the subjects without a measurement in the fast-acting insulin aspart group under investigation evolve less favourably than predicted. As a first step imputations will be done without penalty assuming MAR in the treatment group. Second, a penalty will be added to the imputed values for week 26 in the fast-acting insulin aspart group under investigation. This is done repeatedly, gradually increasing the penalty until the conclusions of the primary analysis no longer hold. The specific value of the penalty that changes the conclusion will be used to evaluate the robustness of the conclusion of the primary analysis.

- 6) A tipping point analysis based on a statistical model using multiple imputation, similar to 5) but with the modification that subjects without a measurement that discontinued treatment due to non-eligibility (subjects discontinuing fast-acting insulin aspart/NovoRapid® prematurely due to criteria 1, 2, 3, and 4) in the fast-acting insulin aspart group under investigation will not have a penalty added to the imputed values. These analyses are motivated by the fact that data from subjects prematurely discontinuing fast-acting insulin aspart/NovoRapid® due to non-eligibility can reasonably be assumed to be missing completely at random. The analysis will use the on-treatment observation period.
- 7) The same statistical model using multiple imputation as the analysis in 4), but using the PP analysis set and analysed using the on-treatment observation period. This analysis will investigate the situation that subjects deviate from the ideal treatment during the on-treatment observation period and will serve as a sensitivity analysis for the non-inferiority analysis.

2.4 Secondary endpoints

2.4.1 Confirmatory secondary endpoints

If the effect of mealtime fast-acting insulin aspart can be confirmed in the primary analysis, the trial also aims to compare treatment arms for a number of confirmatory secondary endpoints.

The steps as stated earlier in Section 2 in the hierarchical testing procedure are:

Step 1 (Primary analysis): HbA_{1c} non-inferiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid®

Step 2: HbA_{1c} non-inferiority of postmeal fast-acting insulin aspart versus mealtime NovoRapid®

Step 3: 1-hour PPG increments superiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid®

Step 4: HbA_{1c} superiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid®

Step 5: 1,5-anhydroglucitol superiority of mealtime fast-acting insulin aspart versus mealtime NovoRapid®

The secondary analysis 4) will also be repeated for the confirmatory secondary endpoints. The analysis will be based on the FAS and using the on-treatment observation period.

Change from baseline in HbA_{1c} 26 weeks after randomisation (step 2)

If the primary objective is confirmed, the effect of treatment with postmeal fast-acting insulin aspart in terms of glycaemic control is to be investigated by showing that post meal fast-acting insulin aspart is non-inferior to NovoRapid[®] both in combination with insulin degludec in terms of glucose lowering effect as assessed by change from baseline in HbA_{1c} 26 weeks after randomisation.

Non-inferiority will be evaluated based on the two-sided 95% CI of mean treatment difference (postmeal fast-acting insulin aspart minus mealtime NovoRapid[®]) obtained from the primary statistical analysis in 1).

Change from baseline in 1-hour PPG increments 26 weeks after randomisation (meal test) (step 3)

As the third step of the hierarchical testing procedure, change from baseline in 1-hour PPG increments (meal test) 26 weeks after randomisation will be tested for superiority of mealtime fast-acting insulin aspart compared to mealtime NovoRapid[®]. The 1-hour PPG increment will be analysed based on the laboratory-measured values in the meal test, and is derived using the 1-hour PPG measurement minus the pre-prandial PG.

The 1-hour PPG increment primary estimand will be addressed using an analysis of variance model (ANOVA) including treatment, region, and bolus adjusting method as factors and 1-hour PPG increment at baseline as covariate. Superiority will be confirmed if the upper boundary of the two-sided 95% CI of the mean treatment difference (mealtime fast-acting insulin aspart minus mealtime NovoRapid[®]) is below 0.

Change from baseline in HbA_{1c} 26 weeks after randomisation (step 4)

As the fourth step of the hierarchical testing procedure, superiority of HbA_{1c} 26 weeks after randomisation with mealtime faster-acting insulin aspart compared to NovoRapid[®] is to be confirmed. The confidence interval from the same statistical model as used for the primary analysis in 1) will be used to determine superiority. Superiority will be confirmed if the upper boundary of the two-sided 95% CI of the mean treatment difference (mealtime fast-acting insulin aspart minus mealtime NovoRapid[®]) is below 0%-points.

Change from baseline in 1,5-anhydroglucitol 26 weeks after randomisation (step 5)

Step 5 in the hierarchical testing procedure is to confirm superiority of changes from baseline in 1,5-anhydroglucitol 26 weeks after randomisation with mealtime fast-acting insulin aspart compared to mealtime NovoRapid[®].

The analysis for the primary 1,5-anhydroglucitol estimand will be done using all subjects included in FAS and using the in-trial observation period. The change from baseline in 1,5-anhydroglucitol will be analysed using a model similar to 1) except with the baseline 1,5-anhydroglucitol as a covariate. Superiority will be confirmed if the upper boundary of the two-sided 95% CI of the mean treatment difference (mealtime fast-acting insulin aspart minus mealtime NovoRapid®) is below 0.

2.4.2 Supportive secondary endpoints

For all supportive secondary endpoints, mealtime fast-acting insulin aspart will be compared to mealtime NovoRapid®, and postmeal fast-acting insulin aspart will be compared to mealtime NovoRapid®, unless otherwise stated.

2.4.2.1 Efficacy endpoints

All endpoints except insulin dose in this section will be assessed using the FAS and the in-trial observation period and repeated using the on-treatment observation period. Insulin dose will be presented using SAS and will therefore only use the on-treatment observation period.

Change from baseline in FPG after 26 weeks of treatment

Change from baseline in FPG 26 weeks after randomisation will be analysed based on all planned post-baseline measurements until or at 26 weeks using a model similar to 1), except with baseline FPG as covariate.

Percentage of Subjects reaching HbA_{1c} target 26 weeks after randomisation:

HbA_{1c} < 7.0%

A dichotomous (responder/non-responder) endpoint will be defined based on whether a subject has met the ADA HbA_{1c} target (HbA_{1c} <7.0%) 26 weeks after randomisation.

This responder endpoint will be analysed based on a logistic regression model using treatment, region, and bolus adjusting method as factors, and baseline HbA_{1c} as covariate. In analysis of the in-trial data, subjects without an HbA_{1c} measurement at week 26 will be treated as non-responders. In the on-treatment observation period analysis, subjects who discontinue fast-acting insulin aspart/NovoRapid® or withdraw from trial or have no HbA_{1c} measurement at week 26 will be included as non-responders.

HbA_{1c} < 7.0% without severe hypoglycaemia

A dichotomous (responder/non-responder) endpoint will be defined based on whether a subject has met the ADA HbA_{1c} target (HbA_{1c} <7.0%) 26 weeks after randomisation without treatment-emergent severe hypoglycaemic episodes.

This responder endpoint will be analysed based on a logistic regression model using treatment, region, and bolus adjusting method as factors and baseline HbA_{1c} as covariate. In analysis of the in-trial data, subjects without an HbA_{1c} measurement at week 26 will be treated as non-responders. In the on-treatment observation period analysis, subjects who discontinue fast-acting insulin aspart/NovoRapid® or withdraw from trial or have no HbA_{1c} measurement at week 26 will be included as non-responders.

HbA_{1c} < 7.0% without severe hypoglycaemia and minimal weight gain (<3.0%)

A dichotomous (responder/non-responder) endpoints will be defined based on whether a subject has met the ADA HbA_{1c} target (HbA_{1c} <7.0%) 26 weeks after randomisation without treatment-emergent severe hypoglycaemic episodes, and with minimal weight gain from baseline to 26 weeks after randomisation (defined as less than a 3% increase).

This responder endpoint will be analysed based on a logistic regression model using treatment, region, and bolus adjusting method as factors and baseline HbA_{1c} and baseline body weight as covariates. In analysis of the in-trial data, subjects without an HbA_{1c} measurement at week 26 or without body weight measurement at week 26 will be treated as non-responders. In the on-treatment observation period analysis, subjects who discontinue fast-acting insulin aspart/NovoRapid® or withdraw from trial or have no HbA_{1c} measurement at week 26 or have no body weight measurement at week 26 will be included as non-responders.

Change from baseline in 30- min, 1- hour, 2- hour, 3- hour and 4- hour PPG and 30- min, 2- hour, 3- hour and 4- hour PPG increment 26 weeks after randomisation (meal test)

Laboratory measured PG from the meal test will be analysed for 30, 60, 120, 180, and 240 minutes PPG separately. The corresponding PPG increments will be derived separately using each PPG measurement minus the pre-prandial PG.

Change from baseline in PPG and PPG increment endpoints 26 weeks after randomisation will be analysed separately using an ANOVA model including treatment, region, and bolus adjusting method as factors, and the corresponding baseline value as covariate.

Note as the meal test is only preformed once post baseline, subjects with no post baseline meal test will not contribute to the analysis.

Change from baseline in 7-9-7-point self-measured plasma glucose (SMPG) profile 26 weeks after randomisation:

In general, analyses will be based on the entire 7-9-7-point profile except for the analyses of nocturnal endpoints where information in the 9-point profile will be utilised. Duration of main meals and time of injection of bolus insulin, which will be collected in connection with 7-9-7 point profiles, will be summarised descriptively.

PPG and PPG increments based on the 7-9-7-point profiles will be derived separately for PG measurements made 1 hour after a meal. In the following section this distinction will be considered implicit and without further explanation.

Pre-prandial PG and PPG will be recorded by the subjects as part of two 7-point and one 9-point SMPG profile prior to the visits. Individual mean mealtime PPG (post-breakfast, post-lunch, post-main evening meal) will be derived from the three profiles. Overall mean PPG will be derived from the individual derived mealtime PPG values.

PPG increment for each meal (breakfast, lunch, main evening meal) will be derived from the 7-point and 9-point profile as the difference between PPG values and the PG value before meal in each separate profile. The mean of the derived increments will then be calculated separately for each meal. Mean 1-hour PPG increments over all meals will be derived as the mean of all corresponding mean meal increments.

Change from baseline in mean of the 7-9-7-point profile

The mean of the 7-9-7-point profile is defined as the area under the curve profile divided by the measurement time, and is calculated using the linear trapezoidal technique.

Change from baseline in the mean of the 7-9-7-point profile 26 weeks after randomisation will be analysed using a model similar to 1) except with the corresponding baseline value as covariate.

Change from baseline in mean PPG and PPG increment over all three meals

Change from baseline in mean PPG and PPG increment 26 weeks randomisation will be analysed separately using a model similar to 1), except with the corresponding baseline value as covariate.

Change from baseline in individual meal (breakfast, lunch and main evening meal) PPG and PPG increment

Change from baseline in PPG and PPG increment endpoints 26 weeks after randomisation for the individual meals (breakfast, lunch, main evening meal) will be analysed separately using a model similar to 1) except with the corresponding baseline value as covariate.

Fluctuation in 7-9-7-point profile

The fluctuation in the 7-9-7-point profile is defined as:

$$\frac{1}{T} \int_0^T |PG(t) - \overline{PG}| dt,$$

where T , $PG(t)$ and \overline{PG} denotes the length of the profile, the PG value at time t and the mean of the profile, respectively.

Fluctuation in the 7-9-7-point profile will be logarithmically transformed and analysed in the same way as the mean of the profile is analysed except with the corresponding log-transformed baseline values as covariate.

Estimated treatment means and the estimated treatment difference with corresponding 95% CI will be back-transformed to the original scale, resulting in estimated geometric means, a treatment ratio and a 95% CI for the treatment ratio.

Change in the nocturnal SMPG measurements

Change from baseline in nocturnal PG values 26 weeks after randomisation will be assessed by considering the differences between PG values available at bedtime, at 4 AM and the before breakfast value the following day: (4 AM PG value minus at bedtime PG value), (before breakfast PG value minus at bedtime PG value) and (before breakfast PG value minus 4 AM PG value).

Change in the nocturnal SMPG measurements will be analysed in the same way as mean of the profile is analysed, except with the corresponding baseline values as covariate.

Percentage of subjects reaching PPG target (based on mean of PPG measurements in SMPG) 26 weeks after randomisation:

Overall PPG (1 hour) ≤ 7.8 mmol/L [140 mg/dL]

A dichotomous endpoint will be defined based on whether a subject has reached an overall mean 1-hour PPG ≤ 7.8 mmol/L [140 mg/dL] 26 weeks after randomisation, where PPG is derived from the 7- and 9-point profile.

This responder endpoint will be analysed based on a logistic regression model using treatment, region, and bolus adjusting method as factors, and baseline overall mean 1-hour PPG as covariate. In analysis of the in-trial data, subjects without an overall mean 1-hour PPG at week 26 will be treated as non-responders. In the on-treatment observation period analysis, subjects who discontinue fast-acting insulin aspart/NovoRapid® or withdraw from trial or have no overall mean 1-hour PPG measurement at week 26 will be included as non-responders.

Overall PPG (1 hour) ≤ 7.8 mmol/L [140 mg/dL] without severe hypoglycaemia

A dichotomous endpoint will be defined based on whether a subject has reached an overall mean 1-hour PPG ≤ 7.8 mmol/L [140 mg/dL] 26 weeks after randomisation without any treatment-emergent severe hypoglycaemic episodes. This responder endpoint will be analysed based on a logistic regression model using treatment, region, and bolus adjusting method as factors, and

baseline overall mean 1-hour PPG as covariate. In analysis of the in-trial data, subjects without an overall mean 1-hour PPG at week 26 will be treated as non-responders. In the on-treatment observation period analysis, subjects who discontinue fast-acting insulin aspart/NovoRapid® or withdraw from trial or have no overall mean 1-hour PPG measurement at week 26 will be included as non-responders.

Overall PPG (1 hour) ≤ 7.8 mmol/L [140 mg/dL] and HbA_{1c} < 7.0% and minimal weight gain (<3.0%) without severe hypoglycaemia

A dichotomous endpoint will be defined based on whether a subject has reached an overall mean 1-hour PPG ≤ 7.8 mmol/L [140 mg/dL], have HbA_{1c} < 7.0% and has had minimal weight gain (increase in body weight from baseline <3.0%) 26 weeks after randomisation, and without any treatment-emergent severe hypoglycaemic episodes.

This responder endpoint will be analysed based on a logistic regression model using treatment, region, and bolus adjusting method as factors, and baseline overall mean 1-hour PPG, baseline HbA_{1c} and baseline body weight as covariates. In analysis of the in-trial observation period, subjects without an overall mean 1-hour PPG or an HbA_{1c} value or a body weight at week 26 will be treated as non-responders. In the on-treatment observation period analysis, subjects who discontinue fast-acting insulin aspart/NovoRapid® or withdraw from trial or have no overall mean 1-hour PPG measurement at week 26 or have no HbA_{1c} measurement at week 26 or have no body weight measurement at week 26 will be included as non-responders.

Insulin dose (basal insulin dose, total and individual meal insulin dose)

The insulin doses will be summarised descriptively by treatment week according to regimen, both by meal type and as total daily dose in units and units/kg (total daily and separately for each mealtime dose). Insulin doses will be summarised using the on-treatment observation period and using the SAS.

Change from baseline in lipids-lipoproteins profile 26 weeks after randomisation (total cholesterol, high density lipoproteins, low density lipoproteins)

Change from baseline in lipid endpoints (low density lipoprotein (LDL), high density lipoprotein (HDL), and total cholesterol) will be analysed separately using a model-similar to 1). The lipid endpoints will be log-transformed before they are analysed including the corresponding baseline measurement which is included in the analysis as a covariate. The treatment difference and associated 95% CIs will be back-transformed providing results in terms of ratios of geometric means on the original scale.

2.4.2.2 Safety endpoints

All safety endpoints will be compared using the on-treatment observation period. In terms of adverse events, as a minimum, serious adverse events will be tabulated separately also using the in-trial observation period.

All events in the in-trial observation period will be listed with information about whether it appeared in the on-treatment observation period or not.

Number of treatment-emergent Adverse Events

AEs will be coded using the Medical Dictionary for Regulatory Activities (MedDRA). AEs will be presented based on system organ class and preferred terms.

A Treatment-Emergent Adverse Event (TEAE) is defined as an event that has an onset date on or after the first day of exposure to randomised treatment, and no later than seven days after the last day of randomised treatment.

TEAEs are summarised descriptively, whereas AE's not defined as treatment-emergent are presented in listings, including AEs reported in the 30-day follow-up period. The summaries of TEAEs are made displaying the number of subjects with at least one event, the percentage of subjects with at least one event, the number of events and the event rate per 100 patient years of exposure. These summaries are done by seriousness, severity, relation to insulin treatment, relation to technical complaint, premature treatment discontinuation due to AEs, withdrawal from trial due to AEs and outcome.

Furthermore, summary tables based on system organ class and preferred terms are made for:

- all TEAEs
- serious TEAEs
- possibly or probably related TEAEs
- severe TEAEs
- TEAEs with preferred term that are experienced by at least 5% of the subjects in any treatment arm or by at least 5% of all subjects

For AEs where additional information is recorded, this will be listed.

AEs occurring during the run-in period are considered non treatment-emergent and will be summarised separately.

Number of treatment-emergent injection site reactions

Treatment-emergent injection site reactions occurring during the trial will be summarised and listed. No formal statistical analysis will be made.

Classification of Hypoglycaemia:

Treatment-emergent: hypoglycaemic episodes will be defined as treatment-emergent if the onset of the episode occurs on or after the first day of IMP administration after randomisation and no later than one day after the last day on IMP.

Nocturnal hypoglycaemic episodes: are episodes occurring between 00:01 and 05.59 both inclusive.

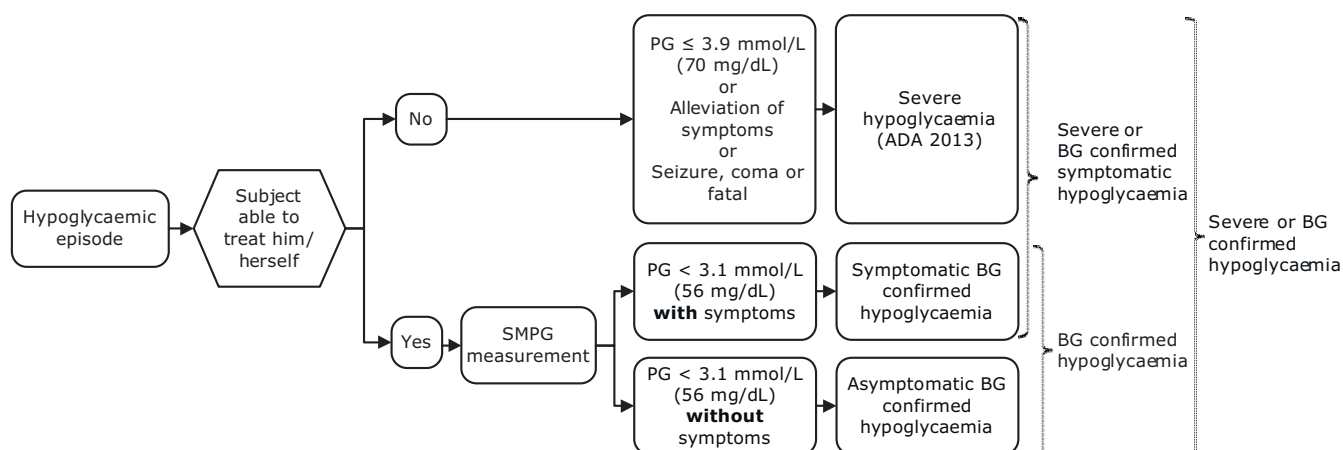

Hypoglycaemic episodes are classified according to the Novo Nordisk classification of hypoglycaemia (see [Figure 2-1](#) and the ADA classification of hypoglycaemia [Figure 2-2](#)).

Novo Nordisk classification of hypoglycaemia

In normal physiology, symptoms of hypoglycaemia occur below a PG level of 3.1 mmol/L (56 mg/dL)³. Therefore, Novo Nordisk has included hypoglycaemia with PG levels below this cut-off point in the definition of blood glucose (BG) confirmed hypoglycaemia.

Novo Nordisk uses the following classification ([Figure 2-1](#)) in addition to the ADA classification:

- Severe hypoglycaemia according to the ADA classification⁴.
- Symptomatic BG confirmed hypoglycaemia: An episode that is BG confirmed by plasma glucose value <3.1 mmol/L (56 mg/dL) **with** symptoms consistent with hypoglycaemia.
- Asymptomatic BG confirmed hypoglycaemia: An episode that is BG confirmed by plasma glucose value <3.1 mmol/L (56 mg/dL) **without** symptoms consistent with hypoglycaemia.
- Severe or BG confirmed symptomatic hypoglycaemia: An episode that is severe according to the ADA classification⁴ or BG confirmed by a plasma glucose value <3.1 mmol/L (56 mg/dL) **with** symptoms consistent with hypoglycaemia.
- BG confirmed hypoglycaemia: An episode that is BG confirmed by a plasma glucose value <3.1 mmol/L (56 mg/dL) **with** or **without** symptoms consistent with hypoglycaemia.
- Severe or BG confirmed hypoglycaemia: An episode that is severe according to the ADA classification⁴ or BG confirmed by a plasma glucose value <3.1 mmol/L (56 mg/dL) **with** or **without** symptoms consistent with hypoglycaemia.

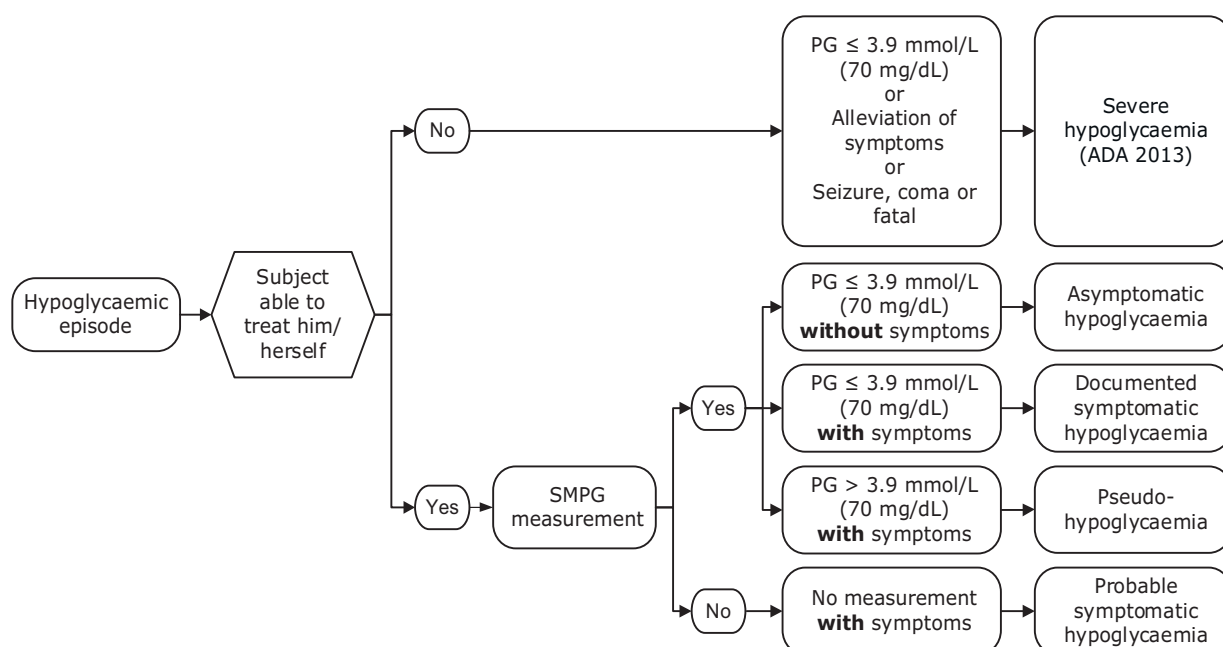

Note: Glucose measurements are performed with capillary blood calibrated to plasma equivalent glucose values

Figure 2-1 Novo Nordisk classification of hypoglycaemia

ADA classification of hypoglycaemia⁴

- Severe hypoglycaemia: An episode requiring assistance of another person to actively administer carbohydrate, glucagon, or take other corrective actions. Plasma glucose concentrations may not be available during an event, but neurological recovery following the return of plasma glucose to normal is considered sufficient evidence that the event was induced by a low plasma glucose concentration.
- Asymptomatic hypoglycaemia: An episode not accompanied by typical symptoms of hypoglycaemia, but with a measured plasma glucose concentration ≤ 3.9 mmol/L (70 mg/dL).
- Documented symptomatic hypoglycaemia: An episode during which typical symptoms of hypoglycaemia are accompanied by a measured plasma glucose concentration ≤ 3.9 mmol/L (70 mg/dL).
- Pseudo-hypoglycaemia: An episode during which the person with diabetes reports any of the typical symptoms of hypoglycaemia with a measured plasma glucose concentration > 3.9 mmol/L (70 mg/dL) but approaching that level.
- Probable symptomatic hypoglycaemia: An episode during which symptoms of hypoglycaemia are not accompanied by a plasma glucose determination but that was presumably caused by a plasma glucose concentration ≤ 3.9 mmol/L (70 mg/dL).

Note: Glucose measurements are performed with capillary blood calibrated to plasma equivalent glucose values

Figure 2-2 ADA classification of hypoglycaemia

Data on treatment-emergent hypoglycaemic episodes are presented in terms of the number of subjects with at least one event (N), the percentage of subjects with at least one event (%), the number of events (E) and the event rate per 100 years of exposure (R). Separate summaries are made by severity considering all episodes, nocturnal and daytime episodes using Novo Nordisk and ADA classified episodes. Episodes will also be summarised overall and by category in relation to time since start of meal, as occurring within the following time intervals:

- During first 1, 2, and 4 hours after start of meal
- Between 1 (exclusive) to 2 hours (inclusive) after start of meal
- Between 2 (exclusive) to 3 hours (inclusive) after start of meal
- Between 3 (exclusive) to 4 hours (inclusive) after start of meal
- Between 2 hours (exclusive) to 4 hours (inclusive) after start of meal

Non-treatment-emergent hypoglycaemic episodes will be listed.

The number of treatment-emergent severe or BG confirmed hypoglycaemic episodes (all, daytime, nocturnal, 1 hour, 2 hour, 4 hour, 1 [exclusive] to 2 hours [inclusive], 2 [exclusive] to 3 hours [inclusive], 3 [exclusive] to 4 hours [inclusive], and from 2 hours [exclusive] to 4 hours [inclusive] after start of meal) will be analysed using a negative binomial regression model with a log -link function and the logarithm of the time period for which a hypoglycaemic episode is considered treatment-emergent as offset. The model will include treatment, region, and bolus adjusting method as factors. To the extent where data allow, separate analyses will be performed for all severe episodes.

Physical examination

The physical examination parameters (head, ears, eyes, nose, throat, neck, respiratory system, cardiovascular system, gastrointestinal system incl. mouth, musculoskeletal system, central and peripheral nervous system, skin), and their change from baseline, will be summarised descriptively in shift tables. All findings will be listed.

Vital signs

Vital signs include diastolic blood pressure, systolic blood pressure and pulse. The measurements will be summarised descriptively using both the actual values as mean change.

ECG

Electrocardiogram (ECG) findings will be summarised descriptively including summaries of the change from baseline. Change from baseline will be summarised as normal/abnormal not clinically significant/abnormal clinically significant categorisation in shift tables.

Fundoscopy/fundus photography

Fundus photography/fundoscopy findings will be summarised descriptively including summaries of the change from baseline. Change from baseline will be summarised as normal/abnormal not clinically significant/abnormal clinically significant categorisation in shift tables.

Clinical laboratory assessments

Change from baseline 26 weeks after randomisation in central laboratory assessments:

Haematology
Biochemistry
Urinalysis

Individual laboratory values will be compared to their relevant reference range (when existing) and flagged as being below or above the range. The measurements will be summarised descriptively using both the actual values as mean change and the low/normal/high categorisation in shift tables.

Change from baseline in anti-insulin aspart (specific and cross-reacting with human insulin) antibody development

The measurements and their change from baseline will be summarised descriptively. The correlation to other relevant variables such as bolus insulin dose and HbA 1c are illustrated using graphs.

Change from baseline in body weight and body mass index (BMI) 26 weeks after randomisation

The measurements will be summarised descriptively using both the actual values and change from baseline.

Change from baseline in body weight will be analysed using a model similar to 1), except with the corresponding baseline measurement as covariate. The analysis will be based on the safety analysis set and the on-treatment observation period.

3 Changes to the statistical analyses planned in the protocol

General considerations

It has been clarified how data collected at visit 36A is handled.

Sample size calculation

Erroneous descriptions in [Table 2-1](#) have been corrected.

Statistical analysis

In the sensitivity analysis 2) for change from baseline in HbA1c, baseline HbA1c has been added to the model as a covariate.

In the statistical analysis in the protocol, it is not clear if missing values or values for subjects discontinuing treatment/withdraw from trial should be imputed. Some of the following changes have been implemented to account for this issue.

In the sensitivity analysis for change from baseline in HbA1c, it has been changed from subjects withdrawing from trial to subjects without a measurement at week 26 to be aligned with the primary analysis.

In the statistical sensitivity analysis 3b) for change from baseline in HbA1c, copy reference has been changed to conditional imputation. Also in the statistical sensitivity analysis for 3c), jump to reference has been changed to unconditional imputation to clarify the method used.

In the statistical analysis addressing the secondary estimand 5) and 6) for change from baseline in HbA1c, tipping point analyses for treatment difference for the comparison between postmeal faster-acting insulin aspart and mealtime NovoRapid® have been added.

It has been clarified that the statistical analysis 4) will be repeated as for the confirmatory secondary endpoints.

In the statistical analysis for percentage of subjects reaching HbA1c or PPG (SMPG) target, it has been clarified that subjects without an HbA1c measurement or 1-hour mean PPG measurement at week 26 will be handled as non-responders in the on-treatment observation period analysis.

In the statistical analysis for percentage of subjects reaching HbA_{1c} target without severe hypoglycaemia and minimal weight gain, it has been clarified that subjects without an HbA1c measurement or a weight measurement at week 26 will be handled as non-responders in the on-treatment observation period analysis.

In the statistical analysis for percentage of subjects reaching HbA_{1c} and PPG (SMPG) targets without severe hypoglycaemia and minimal weight gain, it has been clarified that subjects without an HbA1c measurement or an 1-hour mean PPG measurement or a weight measurement at week 26 will be handled as non-responders in the on-treatment observation period analysis.

In the statistical analysis for treatment-emergent severe or BG confirmed hypoglycaemic episodes, the bolus adjusting method has been added to the model as a covariate.

In the statistical analysis for change from baseline in body weight and BMI, it has been clarified that the analysis will be based on the safety analysis set and the on-treatment observation period.

Fluctuation in 7-9-7-point

Change from baseline has been removed for fluctuation in the 7-7-9-point SMPG profile as it is analysed logarithmically transformed and change from baseline values could be negative.

AEs where additional information is recorded

For AEs where additional information is recorded, this will be only listed.

Hypoglycaemic episodes

The endpoints treatment-emergent hypoglycaemic episodes occurring within 1 (exclusive) to 2 hours (inclusive), 2 (exclusive) to 3 hours (inclusive), 3 (exclusive) to 4 hours (inclusive) after start of the meal have been added to further investigate the safety of fast-acting insulin aspart.

It has been clarified that separate statistical analysis will only be for all severe hypoglycaemic episodes as the number is expected to be very low.

HbA1c at Baseline	

Coefficients for TRTPN Least Squares Means Using WORK.ENDPOINT Margins

	Planned Treatment (N)	Row1	Row2	Row3
Bolus Adjustment Method at Timepoint 1				
		0.3366	0.3366	0.3366
		0.239	0.239	0.239
		0.2937	0.2937	0.2937
BOLUS INSULIN ALGORITHM (SLIDING SCALE)		0.5824	0.5824	0.5824
CARBOHYDRATE COUNTING (FLEXIBLE) BOLUS INSULIN THERAPY		0.4176	0.4176	0.4176
		7.4245	7.4245	7.4245

Subjects achieving HbA1c targets 26 weeks after randomisation - statistical analysis - on-treatment - full analysis set

Parameter Code=HBAB7SHY Parameter=HbA1c <7.0% without severe hypoglycaemic episodes Study Identifier=NN1218-4131

The GENMOD Procedure

TRTPN Least Squares Means

Planned Treatment (N)	Margins	Estimate	Standard Error	z Value	Pr > z	Alpha	Lower	Upper
2	WORK.ENDPOINT	-1.3949	0.1501	-9.29	<.0001	0.05	-1.6891	-1.1006
3	WORK.ENDPOINT	-1.4215	0.1473	-9.65	<.0001	0.05	-1.7103	-1.1327
4	WORK.ENDPOINT	-1.2410	0.1438	-8.63	<.0001	0.05	-1.5228	-0.9591

Differences of TRTPN Least Squares Means

Planned Treatment (N)	Planned Treatment (N)	Margins	Estimate	Standard Error	z Value	Pr > z	Alpha	Lower	Upper
2	4	WORK.ENDPOINT	-0.1539	0.1975	-0.78	0.4358	0.05	-0.5409	0.2331
3	4	WORK.ENDPOINT	-0.1806	0.1947	-0.93	0.3537	0.05	-0.5621	0.2010

Least Squares Means Estimate

Effect	Label	Margins	Estimate	Standard Error	z Value	Pr > z	Alpha	Lower	Upper
TRTPN	Faster aspart (meal) / NovoRapid (meal)	WORK.ENDPOINT	-0.1539	0.1975	-0.78	0.4358	0.05	-0.5409	0.2331

Subjects achieving HbA1c targets 26 weeks after randomisation - statistical analysis - on-treatment - full analysis set

Parameter Code=HBAB7SHY Parameter=HbA1c <7.0% without severe hypoglycaemic episodes Study Identifier=NN1218-4131

The GENMOD Procedure

Least Squares Means Estimate

Effect	Label	Margins	Estimate	Standard Error	z Value	Pr > z	Alpha	Lower	Upper
TRTPN	Faster aspart (post) / NovoRapid (meal)	WORK.ENDPOINT	-0.1806	0.1947	-0.93	0.3537	0.05	-0.5621	0.2010
