

## Study Protocol (Public Version)

### Microbiological and Clinical Effects of Pre- and Probiotics in Non-Surgical Periodontal Therapy (PROPARO)

Protocol ID: **S-477/2024**

Sponsor/PI: **Heidelberg University Hospital, Department of Conservative Dentistry (Poliklinik für Zahnerhaltungskunde) / Prof. Dr. Diana Wolff** (Study Lead)

Version: **v1.0 (Public)** | Date: **25.10.2024**

Study Site(s): **Single-center (Heidelberg University Hospital, Germany)**

Planned Duration: **24 months (recruitment + follow-up)**

## 1. Background and Rationale

Periodontitis is a common chronic inflammatory disease characterized by periodontal pocketing, bleeding on probing, and alveolar bone loss, driven by a dysbiotic biofilm and a dysregulated host response. Standard non-surgical periodontal therapy (NSPT) is primarily mechanical and may be complemented by antiseptics or systemic antibiotics in selected cases. However, routine “microbiome engineering” is not established due to limited high-quality evidence.

Probiotics (live microorganisms conferring a host benefit when administered in adequate amounts) have been investigated as adjuncts to NSPT, with some evidence suggesting improvements in clinical parameters and/or shifts in periodontal pathogens, particularly for *Limosilactobacillus reuteri*. Prebiotics are substrates selectively utilized by microorganisms that may confer a competitive advantage. Vitamin B12 has been discussed as potentially supporting specific microbial metabolic functions relevant to *L. reuteri*. To date, the combined adjunctive use of a probiotic and a prebiotic-acting supplement in NSPT has not been adequately studied with comprehensive microbiome endpoints.

## 2. Objectives and Hypothesis

### 2.1 Primary Objective

To evaluate whether adjunctive oral supplementation with a probiotic (*L. reuteri*)—alone or combined with vitamin B12—modifies the **composition and structure of the supragingival and subgingival oral microbiome** during NSPT.

### 2.2 Secondary Objectives

To compare groups with respect to:

- Periodontal and oral clinical status and inflammatory indicators during standard care
- Patient-level ecological covariates relevant to microbiome composition (diet quality, perceived stress, physical activity)
- Feasibility endpoints (recruitment, adherence, completeness of biospecimen collection)

### 2.3 Hypothesis

Combined supplementation (probiotic + vitamin B12) will produce a **more favorable and sustained shift** of a dysbiotic microbiome toward a more balanced state compared with probiotic alone and compared with standard care without supplementation.

### 3. Study Design

- **Type:** Single-center, randomized, controlled **pilot** study
- **Allocation:** 1:1:1
- **Masking:** **Single-blind** (clinical examiner blinded to group allocation where feasible); participants not blinded (different dosage forms)
- **Control:** Standard care without placebo
- **Framework:** Superiority (exploratory/pilot; hypothesis-generating)

### 4. Participants

#### 4.1 Target Population

Adults with **diagnosed periodontitis (localized or generalized), Stage III or IV**, scheduled for NSPT.

#### 4.2 Inclusion Criteria

- Age  $\geq$  **18 years**
- Stage III or IV periodontitis (localized or generalized)
- Ability to provide informed consent
- Written informed consent including data protection consent

#### 4.3 Exclusion Criteria (key)

- Pregnancy or breastfeeding
- Conditions/medications likely to substantially confound the oral microbiome or periodontal healing (e.g., uncontrolled diabetes mellitus, systemic immunosuppression, chronic steroid use)
- Antibiotic use within the last **3 months**
- Use of oral pre-/probiotic supplements within the last **3 months**
- Recent subgingival instrumentation within the last **6 months**
- Need for obligatory adjunctive systemic antibiotic prophylaxis/therapy for NSPT
- Severe active systemic infection or other conditions judged by investigators to pose undue risk
- Regular use of antiseptic mouthrinses during the study period (unless medically required)
- Strict diets likely to substantially alter baseline microbiome trajectories (e.g., ketogenic, strict vegan) per protocol definition
- Chronic bowel diseases (for systemic confounding considerations)

### 5. Interventions

All groups receive **guideline-concordant non-surgical periodontal therapy (standard care)** including oral hygiene instruction and supportive periodontal therapy (SPT/UPT) follow-up.

## 5.1 Study Arms

**Group 1 (Control):** Standard NSPT/SPT, **no** pre-/probiotic supplementation.

**Group 2 (Test A – Probiotic):** Standard NSPT/SPT **plus** probiotic lozenge containing *L. reuteri* (commercial dietary supplement; **GUM® PerioBalance®**, Sunstar Deutschland GmbH, Schönau, Germany).

- Dosing and duration: **According to manufacturer instructions**, initiated in conjunction with NSPT and continued for **3 months**.

**Group 3 (Test B – Synbiotic-like: Probiotic + Vitamin B12):** Standard NSPT/SPT **plus** the same probiotic regimen **and** vitamin B12 drops (commercial dietary supplement; **natural elements GmbH**, Düsseldorf, Germany).

- Vitamin B12 dosing: **According to manufacturer instructions** (planned daily intake corresponds to 500 µg).
- Duration: **3 months**, aligned with probiotic regimen.

**Re-administration during SPT/UPT:** If clinically indicated subgingival re-instrumentation is performed within routine supportive care, the assigned supplementation regimen may be repeated **as per protocol-defined standardization**.

## 5.2 Concomitant Care and Restrictions

- Standardized toothpaste provided for home use
- Participants follow individualized oral hygiene instructions
- Avoidance of additional antimicrobial adjuncts (e.g., antiseptic mouthrinses) unless clinically required and documented

## 6. Outcomes

### 6.1 Primary Outcome

**Oral microbiome composition (supragingival and subgingival):**

- Global community structure and diversity (alpha/beta diversity measures)
- Relative abundance of taxa/features and functional profiles (as available)

### 6.2 Secondary Outcomes

- Clinical periodontal parameters: PD, CAL, BOP, furcation involvement, mobility grades
- Oral hygiene/gingival indices: Plaque Control Record (O’Leary), Gingival Bleeding Index (Ainamo & Bay)

- Dental status: DMFT
- Patient-reported covariates:
  - Diet quality (DEGS nutrition questionnaire; MEDAS)
  - Perceived stress (PSS)
  - Physical activity (IPAQ)
  - Demographic and socioeconomic information

### 6.3 Safety Outcomes

- Adverse events (AEs) and serious adverse events (SAEs), with particular attention to intolerance to supplements and any unexpected oral/systemic events.

## 7. Study Procedures and Schedule

### 7.1 Study Visits / Time Points

Biospecimens and clinical measures will be collected at **four** standardized time points aligned with clinical care:

1. **Baseline / NSPT start**
2. **Day of full-mouth instrumentation (FMS, per clinic routine)**
3. **Re-evaluation / first SPT visit (~3 months)**
4. **Subsequent SPT visits (~6 and ~12 months)** (as scheduled within standard care)

*(Exact visit windows and operational timing are specified in the internal operations manual.)*

### 7.2 Biospecimens

- **Supragingival plaque**
- **Subgingival plaque**
- **Unstimulated saliva**

All collections use **standard, routine dental sampling approaches**. Detailed collection mechanics (materials, handling, timing, storage logistics) are maintained in **internal SOPs**.

## 8. Laboratory and Bioinformatics (High-level)

### 8.1 Molecular Methods

- **16S rDNA-based profiling** for community composition
- **Shotgun metagenomic sequencing** for species-level resolution and functional inference (where applicable)

### 8.2 Data Processing (High-level)

- Standard quality control, taxonomic assignment, and diversity metrics using validated microbiome workflows
- Differential abundance and multivariable modeling to evaluate group effects while accounting for relevant covariates

*(Parameter-level pipeline specifications, QC thresholds, and code repositories are retained internally and can be shared upon reasonable scientific request after primary publication, consistent with institutional policy.)*

## 9. Sample Size

This is a **pilot feasibility** study. Because robust prior estimates for microbiome change under this specific intervention combination are unavailable, a formal power calculation is not feasible. For feasibility and precision-of-estimate purposes, **n = 60** participants are planned (**20 per arm**).

## 10. Randomization and Allocation

- **Method:** Stratified block randomization
- **Stratification variables:** Sex, age category, and periodontitis diagnosis category
- **Allocation concealment:** Implemented via a pre-generated randomization list managed by authorized study personnel not involved in outcome assessment.

## 11. Blinding

- The **clinical examiner** assessing periodontal endpoints is intended to be **blinded** to group allocation where operationally feasible.
- Participants and dispensing personnel are **not blinded** due to distinguishable supplement forms and the absence of a placebo.

## 12. Statistical Analysis Plan (Public Summary)

### 12.1 Primary Analysis

- Between-group comparisons of microbiome community structure over time using:
  - Diversity metrics (alpha/beta)
  - Ordination-based visualization (e.g., PCoA)
  - Permutational multivariate methods (e.g., PERMANOVA) for group/time effects
- Differential abundance analyses and multivariable models to assess intervention effects while adjusting for relevant covariates (diet, stress, physical activity, smoking status).

### 12.2 Secondary Analyses

- Descriptive statistics for clinical outcomes and patient-reported variables
- Exploratory comparisons of clinical periodontal measures between groups over time (appropriate longitudinal models)

### 12.3 Handling of Missing Data

- Completeness of biospecimens and questionnaires will be summarized
- Analyses will use appropriate methods for missingness consistent with pilot-study reporting

*(A detailed internal SAP exists separately.)*

### **13. Safety Monitoring**

- Participants are monitored for AEs/SAEs at each study contact.
- Supplements used are marketed as dietary supplements in Germany; nevertheless, any suspected supplement-related intolerance or adverse reactions will be documented and managed according to clinical judgment and institutional procedures.

### **14. Ethical Considerations and Data Protection**

- Conducted in accordance with the **Declaration of Helsinki** and applicable German/EU regulations.
- Ethics approval will be obtained from the **Ethics Committee of the Heidelberg Medical Faculty** before study start.
- Written informed consent is required.
- Data will be **pseudonymized**; access to re-identification codes is restricted to the study lead.
- Data and biospecimens will be stored for up to **15 years after publication**, consistent with institutional policy and applicable law.
- Participants may withdraw at any time without disadvantages; handling of already collected data/material follows the consent form provisions.

### **15. Study Status and Dissemination**

- Recruitment begins after ethics approval and site readiness.
- Results will be disseminated via peer-reviewed publication and conference presentations.
- Trial registration will be completed prior to enrollment; primary and key secondary outcomes will be specified prospectively to prevent outcome switching.

### **16. Conflicts of Interest and Funding**

- Conflicts of interest: **None declared** (update if applicable)
- Funding/support: **[insert]** (e.g., institutional resources; clarify if any in-kind supplement provision)
