

## Cover Page for Protocol, Statistical Plan and ICF

<b>Official Title:</b>	Outcomes Comparison Between Baerveldt 350 and Ahmed ClearPath 250 Tube Shunts for the Treatment of Glaucoma
<b>NCT number:</b>	NCT04542616
<b>Document Type:</b>	Statistical Analysis Plan
<b>Date of the Document:</b>	11/1/2024

### Statistical Analysis Plan

#### 1) Roles and Software

All analyses will be performed by the same statisticians from the University at Buffalo Biostatistics, Epidemiology, and Research Design (BERD) team using validated code in R ( $v \geq 4.0$ ) and/or Stata/SAS. Two-sided  $\alpha=0.05$  unless otherwise noted. Versioned scripts and output will be archived.

#### 2) Study Design Summary

Prospective randomized comparative study of eyes undergoing implantation with either Baerveldt 350 mm<sup>2</sup> (B350) or Ahmed ClearPath 250 mm<sup>2</sup> (AC250). Unit of analysis is the eye..

#### 3) Analysis Populations

- **Intention-to-Treat (ITT, primary):** All randomized eyes analyzed by assigned tube shunt implant, regardless of protocol deviations, reoperations, or adjunctive procedures; follow-up contributes until censoring rules apply.

- **Per-Protocol (PP, sensitivity):** Eyes without major protocol deviations and with tube shunt implant received as assigned.
- **Safety Set:** All eyes that underwent study tube shunt implantation.

#### 4) Time Points and Visit Windows

Outcomes summarized at postoperative time points: Day 1 (optional), Week 1, Month 1, Month 3, Month 6, Month 12 and Month 24. Each time point as noted above was specified with a specific window. If multiple observations fall within a window, use the one closest to the nominal time; ties favor the later date.

#### 5) Endpoints & Definitions

##### Primary Outcome

- **Success** through 24 months, defined at each visit as meeting all the following:
  - IOP < **21mmHg** and  $\geq 20\%$  reduction from baseline with/without glaucoma medications
  - No additional glaucoma surgery (slit lamp and in-office procedures are allowed)
  - No loss of light perception vision, endophthalmitis, or any complication requiring additional surgery.
 Success must be confirmed on **two consecutive** visits; failures are persistent thereafter.

##### Key Secondary Outcomes

- Mean IOP (mmHg) reduction at each time point up to 24 months.
- Mean number of IOP-lowering medications at each time point.
- Cumulative complication rates up to 24 months (overall and by type).
- Mean best-corrected visual acuity (VA) in logMAR at each time point.
- **Time-to-first success** and **time-to-first failure**.
- Cox regression for predictors of success and of failure.
- Baseline comparability between treatment groups.

##### Baseline Covariates

Age, sex, eye (OD/OS), glaucoma diagnosis, baseline IOP, baseline VA (logMAR), prior ocular surgeries, lens status, race/ethnicity (if collected), number of IOP medications, and center/surgeon (if applicable).

#### 6) General Principles

- **Clustering by person:** Because an individual may contribute two eyes, longitudinal and survival models will use robust (sandwich) standard errors clustered by patient ID or random effects; sensitivity analyses will repeat models after randomly selecting one eye per person.

- **Distributional choices:** Continuous outcomes assessed for normality; if markedly non-normal, use transformations or nonparametric alternatives as specified. Counts may use Poisson/negative binomial as appropriate.
- **Multiplicity:** Primary endpoint tested once at  $\alpha=0.05$ . Secondary endpoints are exploratory; where families of hypotheses are reported (e.g., multiple time-point comparisons), adjusted p-values (Holm) and 95% CIs will be provided alongside unadjusted results.
- **Missing data:** Mixed-effects models fit under MAR. For survival outcomes, right-censoring at last contact is assumed non-informative. Sensitivity analyses with multiple imputation (m=20) will be performed if >10% outcome data are missing at a key visit.

## 7) Descriptive and Baseline Comparisons

- Continuous variables: mean $\pm$ SD (or median [IQR]); between-group comparisons via t-test or Wilcoxon as appropriate.
- Categorical variables: n (%);  $\chi^2$  or Fisher's exact test.
- **Standardized mean differences (SMDs)** reported to assess balance; SMD $\leq$ 0.10 considered well balanced. No formal hypothesis test is required for baseline similarity, but imbalanced covariates may be included in adjusted models.

## 8) Primary Efficacy Analyses

### 8.1 Procedures for IOP Success Analysis

- **Visit-specific success proportions:** At each postoperative time point up to 24 months, estimate success proportion per group with 95% CIs; compare groups using generalized estimating equations (GEE) with logit link, exchangeable correlation by person, and robust SEs. Report odds ratios (ORs) and p-values.
- **Time-to-first success:** Kaplan–Meier curves by group; log-rank test for unadjusted comparison. Cox proportional hazards models (device as main predictor) will estimate hazard ratio (HR) with 95% CI. Robust variance will cluster by patient. Proportional hazards (PH) checked via Schoenfeld residuals; if violated, report time-varying HR (interaction with log time) or stratified Cox.
- **Adjusted models:** Multivariable GEE (visit-specific) and Cox models will adjust for pre-specified covariates: baseline IOP, diagnosis, prior surgery, age and baseline medications.

### 8.2 Time-to-first Failure

- Failure is defined as IOP > 21 mm Hg or less than 20% reduction below baseline on 2 consecutive follow-up visits after 3 months, IOP  $\geq$  5 mm Hg on 2 consecutive follow-up visits after 3 months, reoperation for glaucoma, or loss of light perception vision.
- Kaplan–Meier and Cox analyses as above (device main effect; robust SEs; PH checks). Present cumulative failure at 6, 12, 18, 24 months with 95% CIs.

## 9) Secondary Efficacy Analyses

### 9.1 Mean Post-Op IOP Over Time

- **Primary longitudinal model:** Linear mixed-effects model (LMM) with random intercept for person (and optionally eye), fixed effects for device, time (categorical), and device×time interaction; adjust for baseline IOP and pre-specified covariates.
- **Pointwise comparisons:** For ClinicalTrials.gov reporting, provide mean±SE at each time point per group and adjusted between-group contrasts with p-values from the LMM (or t-test/Wilcoxon if using cross-sectional summaries only).

### 9.2 Mean Number of IOP-Lowering Medications

- Analyze using LMM (if approximately normal) or mixed-effects negative binomial regression for counts. Same fixed/random effects and device×time interaction as above. Report means (or adjusted means) with 95% CIs per time point and between-group p-values.

### 9.3 Visual Acuity (logMAR)

- LMM as in 9.1 with baseline logMAR adjustment. If ceiling/floor or non-normal residuals, consider robust regression or rank-based mixed models; report adjusted mean differences by time.

### 9.4 Cumulative Complication Rates

- **Any complication:** Cumulative incidence estimated with Kaplan–Meier (time to first complication) and compared by log-rank.
- **By type:** If death or non-glaucoma ocular surgeries are competing risks for some complications, use Fine–Gray subdistribution hazards; otherwise, report proportion with 95% CIs by 24 months and compare with GEE (logit link) across visits.
- **Event rates:** Also report incidence rates per 100 eye-months with Poisson exact CIs; between-group rate ratio via Poisson/negative binomial regression with offset for follow-up time.

### 9.5 Predictors of Success and Failure (Cox Regression)

- Separate multivariable Cox models for success and for failure including device, age, sex, baseline IOP, diagnosis, prior surgeries, baseline meds, lens status, and center/surgeon as fixed effects. Use robust SEs clustered by patient. Assess PH and functional form (restricted cubic splines for continuous covariates when indicated). Report adjusted HRs with 95% CIs.

## 10) Handling Reoperations and Additional Interventions

- **For longitudinal means:** Post-reoperation IOP, VA, and medication data remain in ITT analyses but will be flagged; sensitivity analyses will censor at reoperation date and re-fit primary longitudinal and survival models.
- **For success/failure endpoints:** Reoperation for glaucoma constitutes immediate failure (per definition above).

## 11) Outliers, Protocol Deviations, and Data Quality

- Extreme values will be verified against source data; analyses will be performed with and without outliers for sensitivity if they materially affect results. Major protocol deviations are documented; PP analysis excludes these eyes and is reported alongside ITT.

## 12) Interim Analyses and Data Monitoring

No formal interim efficacy analyses are planned. Safety will be summarized periodically but without hypothesis testing.

## 13) Presentation of Results

ClinicalTrials.gov-compatible tables will include:

- Baseline characteristics (means/SDs or n/% with SMDs).
- Visit-wise means (IOP, meds, VA) by group with adjusted between-group differences and p-values.
- Success/failure KM curves with numbers at risk and HRs (95% CI).
- Cumulative complication summaries (overall and by type).
- Multivariable model outputs (betas/HRs, 95% CIs, p-values).
- Pre-specified sensitivity and subgroup analyses.
