

Study Title: Neurobiological Drivers of Mobility Resilience: The Dopaminergic System

PI: Fay Pongmala, PhD

Study ID: HUM00156490

NCT#: NCT06587217

Protocol Version IRB Approval Date: 3/4/2026

Neurobiological drivers of mobility resilience: the dopaminergic system

1. SPECIFIC AIM

Walking with age becomes both slower and less 'automated', requiring more attention and prefrontal resources^{1,2}. As a result, older adults have a greater risk of adverse mobility outcomes and falls. Walking disturbances in the elderly have been linked to changes in both cerebral, in particular small vessel disease (cSVD), and peripheral systems³. There is an urgent need to identify factors that can help compensate for these harmful factors and reduce walking impairments, as there are currently no effective treatments available. Although effective mobility is the end result of the functional capacity of both central and peripheral systems, the brain's unique modulatory and adaptive capacity may provide clues for novel interventions. For example, we have recently discovered that ~20% of older adults maintain fast walking speed even in the presence of age-related cSVD and peripheral system impairments, thus appearing resilient to these harmful factors. Our work suggests that the nigrostriatal dopamine (DA) system may be a source of this resilience. As our recent findings suggest, DA neurotransmission positively predicts walking speed⁴; it also attenuates the negative effects of age-related cSVD and peripheral system impairments on walking speed. These findings are consistent with post-mortem evidence that a combination of loss of nigral DA neurons and cSVD best predict age-related walking impairment⁵⁻⁷. The nigrostriatal DA system plays a critical role in motor control; nigrostriatal DA neurotransmission regulates the automated execution of overlearned motor tasks via its connections with sensorimotor cortical and subcortical areas⁸.

We hypothesize that higher nigrostriatal DA neurotransmission drives resilience to cSVD and peripheral system impairments, via higher connectivity of sensorimotor networks, thus increasing automaticity of walking and reducing prefrontal engagement while walking. Resilience due to the nigrostriatal DA system is a novel and highly promising area of inquiry. Unlike cSVD and brain structural impairments, DA neurotransmission is potentially modifiable, thereby offering novel approaches to treat non-resilient elderly in a targeted fashion. This translational pilot study will use a biomechanistic target engagement study mechanisms targeting dopamine using Carbidopa / Levodopa (C-L Dopa) administration in low DA non-resilient elderly with minimal parkinsonian symptoms (MPS, such as slow walking) to determine change in synaptic DA in relationship to brain imaging connectivity changes and quantitative spatiotemporal kinematic motor tests.

Recently, the first commercially available diagnostic tool for identifying alpha synuclein in cutaneous nerve fibers has been developed by CND Life Sciences (Syn-One Test™). While traditional methods of identifying α -synuclein in cerebrospinal fluid and serum have not proven diagnostically reliable²⁴, recent skin biopsy tests have demonstrated more than 90% sensitivity and specificity in synucleinopathies²⁵. Skin biopsies have shown α -synuclein aggregation in over 80% of patients with idiopathic REM sleep behavior disorder (iRBD), which is currently the most clearly defined preclinical stage of LBD²³. This indicates the accumulation of α -synuclein begins a decade to fifteen years prior to the onset of LBD²³. On this basis, we hypothesize that elderly adults with parkinsonian signs, without a diagnosis of a synucleinopathy, may have alpha synuclein present in peripheral nerve fibers.

Exploratory AIM: Does increased DA neurotransmission in non-resilient elderly with parkinsonian signs (incl. gait <1.0msec) with MPS affect spatiotemporal kinematics, such as cadence or double support time in a mechanistic target engagement study?

Exploratory H1: One week of C-L Dopa treatment will change spatiotemporal kinematics, such as cadence or double support time, by increasing DA in elderly with parkinsonian signs.

Exploratory H2: C-L Dopa treatment will have a biomechanistic effect on functional and metabolic mobility networks in the brain through increasing DA in elderly with parkinsonian signs.

Exploratory H3: Elderly adults with parkinsonian signs will have alpha synuclein accumulating in skin peripheral nerve fibers.

Exploratory H4: C-L Dopa treatment will have biomechanistic effect on skeletal muscle biomarkers

2. BACKGROUND

Rationale. This exploratory mechanistic target engagement study will assess the effect of brief DA supplementation on dopamine availability, nigro-striatal functional connectivity and mobility in a sample of older adults with parkinsonian signs.

The study will screen elderly people for the presence of slow walking (not explained by peripheral or musculoskeletal reasons) and/or other parkinsonian signs. Subjects will be contacted for participation in this study from an existing database in the lab. However, if enough subjects can't be recruited from this database then subjects will be recruited through external sources, such as a flyer posting, online registries, and the University of Michigan Movement Disorders Clinic and other physicians. These subjects will be screened using the telephone screening script, and after this screening they will be brought into the lab to screen for the presence of slow walking and/or other parkinsonian signs. If the clinical assessment does not show evidence for these parkinsonian signs then the person will be excluded from the C-L Dopa and imaging portions of the study (see study outline below).

We will record eligibility, adherence, and tolerability to 1-week supplementation (3 days of carbidopa monotherapy and 7 ± 3 days of C-L Dopa at one tablet PO TID for three days followed by an increase to 1.5 tablets PO TID the next day for the next 4 days (± 3 days)), and the effects of C-L Dopa on mechanistic imaging measures of DA sensorimotor functional connectivity and on clinical mobility functions. This translational aim will provide preliminary information about the targeted modifiability of the DA system in non-resilient elderly with parkinsonian signs.

After the completion of the open-label study, we will be conducting a placebo-controlled, double-blinded study to further examine mechanistic measures of spatiotemporal gait measures, and sensorimotor functional connectivity s through dopamine supplementation via C-L Dopa. Participants in this sub-study will receive the same assessments as those in the open-label study.

After the completion of the placebo-controlled sub-study, we will conduct an additional open-label study to further examine mechanistic spatiotemporal gait measures and

sensorimotor functional connectivity through DA supplementation, with the addition of skeletal muscle testing and other markers before and after DA supplementation.

3. RESEARCH PLAN

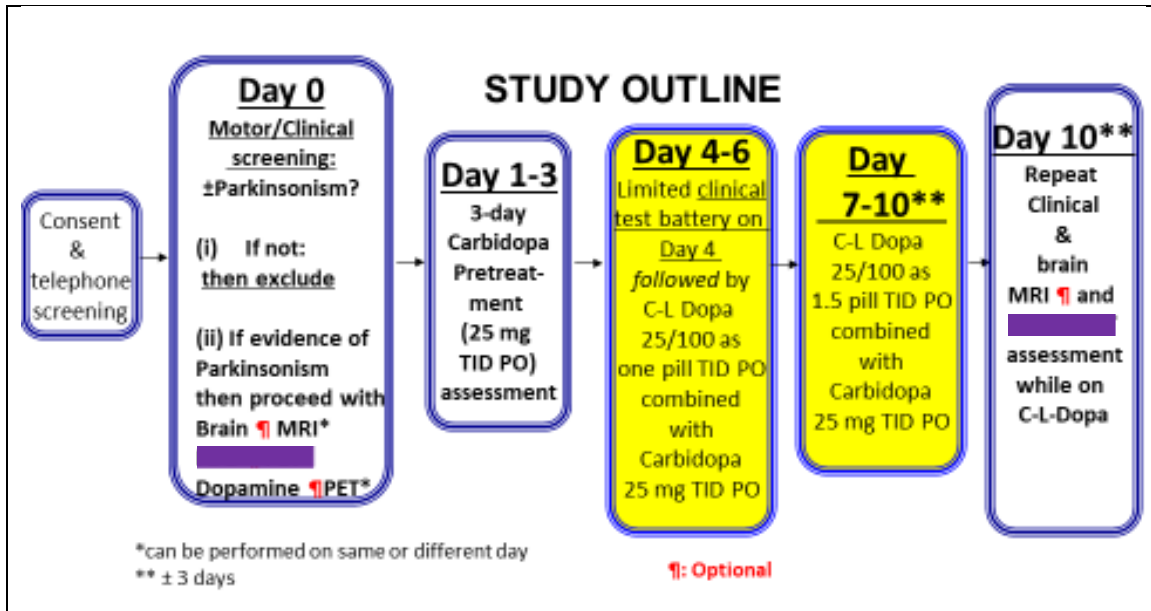

General Overview:

Study design:

1. **Parent Study:** Open-label study. An outline of the study is shown in Figure 1. After obtaining informed consent, subjects (max n=60) will undergo a screening exam to assess for parkinsonian signs, including slow walking speed. Elderly subjects without evidence of parkinsonian signs will be excluded from the C-L dopa and imaging portions of the study.

Eligible subjects with evidence of parkinsonism (max n=20) will then complete a motor, including gait, cognitive test battery), and 3T brain MRI (optional) prior to starting the C-L Dopa treatment portion of the study (Refer to Table 1 and Table 3). Subjects will be pre-treated with carbidopa monotherapy 25 mg TID PO for 3 days. Prior to initiating C-L Dopa 25/100 one tablet PO TID for three days subjects will repeat a limited clinical test battery on day 4. Subjects will then increase to 1.5 tablets PO TID on day 7 (i.e., day 4 of C-L Dopa treatment) for the next 4 days (± 3 days). Carbidopa monotherapy will be given to prevent possible side-effects of nausea and participants will stay on 25 mg carbidopa PO TID for the duration of the treatment period of the study. Participants are given the option to be clinically observed in the lab for their first dosage of C-L Dopa. This optional observation would be 60-120 min in length where the participant will take their first dose of C-L Dopa and be monitored by study personnel. After the week-long (± 3 days) C-L Dopa 25/100 trial the complete test battery will be completed. A [^{11}C]PE2I dopamine PET scan will be performed for assessment of overall nigrostriatal degeneration. This target engagement study will allow for biomechanistic assessment of hypothesized changes in the DA sensorimotor network and will allow us to correlate the C-L Dopa mechanistic effects on DA sensorimotor connectivity changes before/after target engagement as assessed with multimodal graph analytical network methods using optional post-treatment MRI of key relevant circuits related to DA. Dopamine PE2I PET scan will be used for post hoc covariate effects.

Figure 1. Open-Label Study outline.

2. Sub-study 1: Double-blinded, placebo-controlled study. After obtaining informed consent, subjects (max n=40) will undergo a screening exam to assess for parkinsonian signs, including slow walking speed. Elderly subjects without evidence of parkinsonian signs will be excluded from the C-L dopa and imaging portions of the study.

Eligible subjects with evidence of parkinsonism (max n=12, n=6 in each group) will then be randomized to either receive a placebo or the active form of C-L Dopa. Participants will be randomized according to gender and age (+/-7 years). These subjects will then complete a motor, including gait, and cognitive test battery prior to starting the C-L Dopa supplementation portion of the study. These participants will have the option to complete a skin biopsy procedure to look for alpha synuclein in peripheral nerves at any of their three visits. Subjects will be pre-treated with carbidopa monotherapy 25 mg TID PO or the placebo TID PO for 3 days. Participants in both groups will receive the same number of tablets and follow the same administration schedule. Prior to initiating C-L Dopa 25/100 or placebo one tablet PO TID for three days subjects will repeat a limited clinical test battery on day 4. Subjects increase to 1.5 tablets C-L Dopa PO TID on day 7 (i.e., day 4 of C-L Dopa supplementation) for the next 4 days (±3 days). Carbidopa monotherapy will be given to prevent possible side-effects of nausea and participants will stay on 25 mg carbidopa PO TID for the duration of the supplementation period of the study. Participants are given the option to be clinically observed in the lab for their first dosage of C-L Dopa or placebo. This optional observation would be 60-120 min in length where the participant will take their first dose of C-L Dopa and be monitored by study personnel. After the week-long (±3 days) C-L Dopa 25/100 trial the complete test battery will be completed. A [¹¹C]PE2I dopamine PET scan will be performed for assessment of overall nigrostriatal degeneration in addition to a 3T brain MRI (optional). These scans can occur before, during, or after the intervention.

3. Sub-study 2: Open-label study. After obtaining informed consent, subjects (max n=20 to allow for screen failures or attrition) will undergo a screening exam to assess for parkinsonian signs, including slow walking speed. Elderly subjects without evidence of parkinsonian signs will be excluded from the C-L dopa and imaging portions of the study.

Eligible subjects with evidence of parkinsonism (max n=6 for net study completion) will then complete a test battery involving motor testing, muscle testing, cognitive testing, fasted blood draw, and muscle biopsy prior to starting the C-L Dopa supplementation portion of the study. Subjects will be pre-treated with carbidopa monotherapy 25 mg TID PO for 3 days. Participants will repeat a limited clinical test battery on day 4 prior to initiating the C-L Dopa 25/100 TID. Subjects increase to 1.5 tablets C-L Dopa PO TID on day 7 (i.e., day 4 of C-L Dopa supplementation) and continue for the next 4 days (± 3 days). Carbidopa monotherapy will be given to prevent possible side-effects of nausea and participants will stay on 25 mg carbidopa PO TID for the duration of the supplementation period of the study. Participants are given the option to be clinically observed in the lab for their first dosage of C-L Dopa. This optional observation would be 60-120 min in length where the participant will take their first dose of C-L Dopa and be monitored by study personnel. After the week-long (± 3 days) C-L Dopa 25/100 trial the complete test battery including fasted blood draw and muscle biopsy will be repeated. A [^{11}C]PE2I dopamine PET scan will be performed for assessment of overall nigrostriatal degeneration in addition to a 3T brain MRI (optional). These scans can occur before, during, or after the intervention.

Subjects who completed the parent study or sub-study 1 may be invited to participate in sub-study 2.

Subjects:

Eligibility: Non-resilient elderly non-PD subjects (F/M, age 60 yrs or older) with evidence of mild parkinsonian signs (MPS, slow gait ($< 1\text{m/s}$)). The UPDRS motor component (part III) will be used to assess for evidence of parkinsonian signs, including bradykinesia, tremor, rigidity, and gait disturbances.

Inclusion:

- 1) Age 60 or older (M/F)
- 2) Evidence of mild parkinsonian signs (incl. MPS, slow gait ($< 1\text{m/s}$))

Exclusion:

- 1) Evidence of prior established diagnosis and/or treatment for PD¹³.
- 2) Presence of clinically significant degenerative joint disease and/or neuropathy interfering with proper assessment of the motor UPDRS exam.
- 3) Presence of significant dementia.
- 4) History of stroke with residual clinical deficit interfering with walking.
- 5) For optional MR imaging only: Participants in whom magnetic resonance imaging (MRI) is contraindicated including, but not limited to, those with a pacemaker, presence of metallic fragments near the eyes or spinal cord, or cochlear implant.
- 6) For optional brain imaging only: Severe claustrophobia precluding neuroimaging procedures.
- 7) Participants that have been on monoamine oxidase inhibitors (MAOIs) within 2 weeks prior to starting study.
- 8) Inability to stand or walk without an assistive device
- 9) Hypersensitivity to the carbidopa, levodopa, and tablet components.
- 10) History of myocardial infarction (MI) with residual arterial, nodal or ventricular arrhythmia

- 11) History of peptic ulcer
- 12) Chronic wide angle glaucoma
- 13) Narrow angle glaucoma
- 14) Major psychotic disorder
- 15) Severe cardiovascular or pulmonary disease, bronchial asthma, renal, hepatic or endocrine disease
- 16) Subjects on dopamine D2 receptor antagonists, dopamine depleting agents, and metoclopramide.
- 17) Any other medical history determined by investigators to preclude safe participation.
- 18) For sub-study 1 optional skin biopsy and sub-study 2 muscle biopsy only:

1. Subjects who are dependent on alcohol
2. Subjects who are unable/unwilling to refrain from nicotine/tobacco use for 12 hours prior the biopsy procedure
3. Subjects who are taking certain blood thinners or anti-coagulant medications may be excluded from the biopsies. Aspirin or Plavix are considered safe, it will up to the discretion of the investigators to review medications to confirm eligibility.
4. Subjects who have a history of allergic reaction to local anesthesia for skin biopsies
5. Subjects with significantly impaired wound healing or history of scarring or keloid formation
6. Subjects whose synucleinopathy may be explained by other causes:
 - a. Cortical dementia of Alzheimer's type
 - b. Encephalitis
 - c. Whipple's disease
 - d. Toxin exposure
 - e. Repeated head injury
 - f. Stepwise disease progression suggestive of vascular etiology

Study Timeline:

The open-label study will be performed over 2 years with anticipated net recruitment and completion of half of the subjects per year. A milestone of success will be recruitment of 5 subjects who have completed the CL Dopa treatment by the end of year 1. The last 2 months will be used for data analysis and report writing.

The placebo-controlled study (sub-study 1) will be performed over 2 years with anticipated net recruitment and completion of half of the subjects per year. The last 2 months will be used for data analysis.

Sub-study 2 will be performed over 1 year with anticipated net recruitment and completion of all 6 subjects within 10 months. The last 2 months will be used for data analysis and report writing.

Dissemination plan:

Study findings will be published in peer-reviewed journals and presented at scientific meetings.

Design: Within-subject study design using after-before difference measures.

Sample size: This is an exploratory pilot project to generate sample size effects for future larger scale studies, with a net study completion goal of 20 treated subjects for the open-label and 12 subjects for the placebo-controlled study (sub-study 1). The net study completion goal for the muscle testing study (sub-study 2) will be 6 treated subjects.

Impact: This project will elucidate the neurobiology of gait slowing at spatiotemporal kinematics, structural and functional levels of analysis, increasing our understanding of the interplay between these aging-associated processes and the brain network changes underlying late life mobility disorders. Additionally, if elderly adults with parkinsonian signs have alpha synuclein in their peripheral nerve fibers, they may be in the early stages of a synucleinopathy. Lastly, this study aims to elucidate the relationship between skeletal muscle biomarkers and motor performance in older non-resilient adults without Parkinson's and examine the relationship between DA neurotransmission and muscle health.

Table 1: Main components of the Test Battery, including detailed gait and balance assessments		
<u>Test</u>	<u>Primary outcome parameter</u>	<u>Admin. Time</u>
<u>Gait:</u> Timed walking tests (single & dual task gait). Optional: Electronic gait assessments using mats (Zeno Walkways, Protokinetics) and/or sensors (APDM) under single and dual test conditions and challenged gait.	Assessment of standard spatiotemporal gait parameters & variability measures	2 min
<u>Dynamic balance:</u> Mini-BESTest ³ , with optional APDM sensors	Total Mini-BESTest score	15 min
<u>Balance confidence/fear of falling:</u> The Activities-specific Balance Confidence (ABC) scale ⁴	Total ABC score	5 min
<u>Cognitive-motor dual task: Stroop stepping mat</u>	Errors and reaction time	10 min
		<i>Total: 45 min</i>

Primary Outcome variables, open-label study:

- (a) Biomechanical gait and postural parameters
- (b) Cognition (see Table 2)

Primary Outcome Measure: Placebo-controlled study (sub-study 1):

- (a) Gait speed as measured during iTUG portion of the Mini-BESTest

Secondary Outcome Measures: Placebo-controlled study (sub-study 1):

- (a) Parkinson's disease cognitive rating scale (PDCRS) total score
- (b) Stroop stepping mat: reaction time and total errors

Primary Outcome Measure: Open-label muscle testing study (sub-study 2):

- (a) Gait speed as measured during iTUG portion of the Mini-BESTest

Exploratory Outcome Measures: Open-label muscle testing study (sub-study 2)

- (a) Quantify the change in blood extracellular vesicle (EV) levels after 1-week C-L Dopa supplementation.
- (b) Skeletal muscle biomarkers
- (c) Mean torque value for each leg during Biodex muscle strength test.
- (d) Cognition (see table 2)

Study Treatment:

Carbidopa Monotherapy: Due to the small risk of nausea and vomiting from taking C-L Dopa, all subjects will be pretreated with carbidopa 25 mg orally (PO) three times a day (TID) monotherapy for 3 days prior to starting C-L Dopa.

C-L Dopa administration: A low dose (25/100 1 tablet orally (PO) three times a day (TID) of C-L Dopa immediate release will be used for the first three days of C-L Dopa treatment then if no side-effects will be increased on day 4 of the C-L Dopa treatment to 1.5 pills TID PO. All participants will continue to take carbidopa 25 mg TID PO for the whole duration of the treatment period.

Drug Supplies: Formulation, Preparation and Dispensing

Carbidopa Monotherapy:

Carbidopa will be prepared and dispensed by the Research Pharmacy at the University of Michigan.

C-L Dopa:

C-L Dopa will be prepared and dispensed by the Research Pharmacy at the University of Michigan.

Placebo:

The placebo will be prepared and dispensed by the Research Pharmacy at the University of Michigan.

Drug Storage and Drug Accountability

Carbidopa Monotherapy: Drug will be stored and accounted for at the Research Pharmacy at the University of Michigan per their established standing operating procedures.

C-L Dopa: Drug will be stored and accounted for at the Research Pharmacy at the University of Michigan per their established standing operating procedures.

Placebo: Drug will be stored and accounted for at the Research Pharmacy at the University of Michigan per their established standing operating procedures.

Concomitant Medications

Use of both carbidopa monotherapy and C-L Dopa, has been contraindicated with concurrent use with nonselective monoamine oxidase inhibitors (MAOIs) or use within the last 14 days.

Use of C-L Dopa with concurrent antihypertensive medications may increase the risk of symptoms related to orthostatic hypotension. Study staff will closely monitor participants and ask them to discontinue C-L Dopa if severe symptoms present.

Concomitant use of phenytoin and papaverine may reduce indicated effects of C-L Dopa. However, the use of these medications with C-L Dopa does not present any additional risks.

Other Considerations

High protein diets have the potential to impair C-L Dopa absorption as the levodopa ingredient competes with certain amino acids for transport across the gut wall or across the blood-brain barrier. For this reason, participants will be instructed to take the study drugs at least ½ hour before each meal (i.e., breakfast, lunch & supper). However, the pre-meal intake of these drugs can be combined with non-proteinaceous supplements, like fruit juices or fruits (banana, apple sauce, etc.).

Iron salts or multi-vitamins containing iron salts have the potential to decrease the bioavailability of carbidopa and levodopa. Participants taking iron salts will be asked to supplement at the end of the day to minimize the potential C-L Dopa absorption reductions.

Clinical Testing:

Clinical assessment (see also Table 3) includes a general demographic, medical and, neurological examination, the measurement of visual acuity, (optional) visual contrast sensitivity (Rabin test), (optional) color blindness (Munsell 15), orthostatic vital signs, weight and height in all subjects, general motor assessment, including the Movement Disorder Society revised UPDRS examination (13), modified Hoehn & Yahr (14) to provide assessment of general motor impairments of PD. Questionnaires to assess overall sedentarism and physical activity will be administered. Detailed cognitive testing will also be performed.

Functional assessment of motor features:

Several well-validated balance, gait, and fall-associated scales and tests will be used to further assess functional mobility 7 (see Table 3). In addition to these motor examinations we will also use questionnaires to assess for the presence of gait festination and freezing of gait ¹⁵⁻¹⁷. In addition, finger tapping and Grooved Pegboard testing will be used to provide quantitative measures of upper limb bradykinesia and motor dexterity. Optionally, foot tapping will be used as a measure of lower limb bradykinesia. A specialized mobility and postural control test battery to capture gait and postural functions will also be performed. Some tasks may be performed while performing a secondary cognitive task (e.g. counting backwards by 3s).

Muscle Strength Testing:

Biodex Strength Test: Participants will sit (~85° hip flexion) on an ergometer (Biodex System 4). The upper body will be stabilized with straps across the thorax and abdomen. Knee joint axis of rotation will be aligned with the measurement axis of the system. The leg being tested will be strapped around the mid-thigh. The knee angle will be placed at 90° to cancel the effect of gravity on the test. Participants will be instructed to perform

maximal effort during a static knee extension and to limit countermovement. At least three maximal voluntary contractions will be recorded. A fourth and possibly fifth trial will be performed if the value reached during the last trial is higher than the preceding ones, or if the difference between trials was greater than 10%. Participants will be encouraged verbally throughout the test. Biodex testing for isometric strength is established as the gold standard in the field and highly reliable²⁸. Protocol for biodex isometric testing on knee extensors taken from prior studies at University of Manitoba²⁹.

Grip strength will be measured using a handheld Dynamometer.

Muscle Testing will be assessed during visit 1 only.

Biological samples:

Optional saliva samples may be collected for analysis of dopamine and other related genotypes for the open-label study only. Samples will be processed and analyzed at laboratories the Department of Human Genetics, or at other intra- or extramural institutions. (For sub-study 1 only) Tissue samples may be collected via a biopsy procedure. Deidentified samples will be sent to CND Life Sciences Laboratory which will stain the tissue for alpha synuclein. The distribution of alpha synuclein and nerve fiber density will be evaluated.

Skeletal Muscle Biopsy (sub-study 2 only)

The modified muscle biopsy technique was introduced nearly 60 years ago [22] and is a fundamental component of muscle health research (e.g., insulin sensitivity, inflammation). This technique is used commonly in the medical research field (as indicated by large scale consortiums [e.g., NIH funded MoTrPAC]) and is currently utilized at the University of Michigan. Members of the research team have been involved with muscle biopsies for ~15 y, totaling >1000 muscle biopsies in populations including athletes, elderly, obese, type 2 diabetics³¹⁻³³. Dr. Jacob Haus, PhD will perform the muscle biopsies which are critical to completion of study objectives.

Muscle biopsies will be obtained before and after the 1-week C-L Dopa supplementation period. Muscle samples (~200 mg; approximately the size of a pea) will be obtained from the *vastus lateralis* muscle (thigh muscle) following local anesthetic delivery using the modified muscle biopsy technique^{30,31,32,34}. Muscle tissue will be quickly trimmed of excess connective tissue and fat, blotted with gauze to remove blood, and processed specific to future analysis. Subjects will be instructed on how to care for the wound and supplied with ice and pressure bandages after each biopsy to reduce inflammation and any soreness. A member of the research team will follow-up with each participant the day after a muscle biopsy. All muscle biopsies will be performed and analyzed in laboratories within the University of Michigan. Participants who use tobacco/nicotine will be asked to refrain from use for at least 12 hours prior to the biopsy procedure.

Blood Sampling

Blood samples will be obtained before and after the 1-week C-L Dopa supplementation period for assessments of extracellular vesicles (EV). ~20mL of whole blood will be collected at each timepoint for analysis. Participants will be asked to arrive to the laboratory in a fasted state for the blood draw.

. Plasma will be separated from blood samples collected in vacutainer tubes via centrifugation before and after 1-week C-L Dopa supplementation.

Extracellular vesicle (EV) analysis will be performed at the laboratory of Dr. Gagan Deep at Wake Forest University (Winston-Salem, North Carolina). Plasma samples will be deidentified, then shipped to Dr. Deep at which point total EVs (TE) will be isolated from the plasma using a modified precipitation method described previously^{34,35}. A material transfer agreement (MTA) will be established prior to shipment of any samples.

One extra tube of blood will be stored for additional analysis if needed.

Neurocognitive and functional status assessments:

Table 2 provides an overview of the detailed neuropsychological examination. We will assess global cognitive changes over time based on the MMSE¹⁸, MoCA¹⁹, and a composite z-score encompassing the major cognitive domains from the test battery.

Table 2. Components of the neuropsychological test battery	
Overall mental status	Optional: Mini Mental State Exam ¹⁸ Montreal Cognitive Assessment Scale ¹⁹ Parkinson's disease cognitive rating scale ²⁶
Attention	D-KEFS: Trail Making Test, Stroop Color Word Interference Test ²⁰
Learning & Memory	Optional: California Verbal Learning Test – II ²¹
Executive/Working Memory	D-KEFS: Trail Making Test
Information processing speed	D-KEFS: Trail Making Test ²⁰ Digit Symbol test, Optional: Reaction time Optional: Falling stick test

MR imaging (optional): MR imaging will be performed on a 3 Tesla Philips Achieva system (Philips) utilizing a 15-channel head coil and the 'ISOVOX' exam card protocol primarily designed to yield isotropic T₁ spoiled gradient (SPGR) spatial resolution. This protocol consists of a number of different sequences including a standard T₁-weighted series of a 3D inversion recovery-prepared turbo-field-echo will be performed in the sagittal plane with repetition time/echo time/inversion time = 9.8/4.6/1041 ms; turbo factor = 200; single average; field of view = 240 x 200 x 160 mm; acquired matrix = 240 x 200. Slices (n = 160) will be reconstructed to 1mm isotropic resolution. This sequence maximizes contrast among grey matter, white matter and CSF and provides high resolution delineation of cortical and subcortical structures. Other standard sequences include FLAIR, DTI, resting state functional connectivity MRI, or other relevant series. The brain MRI scan can be performed on the same day as the clinical assessment or anytime throughout the supplementation period.

PET imaging: All PET data will be acquired at the University of Michigan PET facility on a Siemens BioGraph TruePoint Model 1094 PET/CT scanner, which produces 109 slices, has an axial field-of-view of 22.0 cm with slice thickness of 2.027 mm, and intrinsic image resolution 4.2 mm full-width at half maximum (FWHM). Image reconstruction for both tracers will be done with fully 3D-iterative OSEM, using 4 iterations, 16 subsets, and post-reconstruction files of 3.0 mm FWHM, yielding images of ~5.0 FWHM. One low-dosage CT scan (130 kVp, 30 eff mAs, 6 x 3mm collimation, pitch =1, rotation time =0.6 second) of the head will be performed prior to each brain PET

scan for attenuation correction purposes. “As low as reasonably achievable” (ALARA) techniques will be utilized to minimize subject radiation exposure.

Subjects will be studied supine, with eyes and ears unoccluded, resting quietly in a dimly lit room. [¹¹C]PE2I PET ligand are non-approved radiopharmaceutical that will be used in accordance with Food and Drug Administration regulations (21 CFR 361.1). All tracers are prepared following standard synthesis routines at the University of Michigan PET Chemistry and Cyclotron facilities.

Daily life activity levels (optional): Overall activity levels during medication therapy will also be assessed. Subjects will be asked to wear an accelerometer based actigraphy device (Actigraph or ActivPAL) for the duration of the carbidopa monotherapy and carbidopa-levodopa mechanistic study.

Compliance Monitoring Phone Call: A compliance phone call will be performed by a research staff member during the 7 day \pm 3 C-L Dopa medication stage.

Timeline: Refer to table 3 for timeline and test details. Day 0 may be completed over multiple visits. Once all tasks listed under Day 0 are completed Day 1 will start. Day 9(\pm 3) tasks will be performed while participant is still taking C-L Dopa and may require multiple visits.

Analysis:

Statistical analysis: For all studies and sub-studies, we anticipate that 90% of eligible subjects will complete the 1-week C-L Dopa supplementation; the effect of C-L Dopa administration on brain connectivity and mobility measures will be tested using a repeated measures design.

Data safety-monitoring plan: This study will adhere to a data safety-monitoring plan where the principal investigator will be responsible for regular (at least annual) monitoring of general progress of the study, such as subject recruitment, perform interim statistical analysis on the data (only when statistically feasible), review of outcome and adverse event data to determine whether there is any change to the anticipated benefit-to-risk ratio (which may require modification or termination of the study protocol), assessment of external scientific or medical developments that may have an impact on the safety of study participants or the ethics of the study. Dr. Amelia Heston, Instructor of Neurology, will serve as an independent safety officer and will review twice yearly safety reports. The monitoring process will also include a review of study procedures aimed at the protection of the privacy of the research subjects and confidentiality of the research data. Adverse events will be reported to the IRB adverse events reporting guidelines. If the protocol needs to be modified or there is a change in the level of risk to subjects for this study, a modification submission will be prepared for review by the IRB. All data collected on research subjects will be kept confidential as detailed above.

All study staff will be extensively trained in test administration to ensure the integrity of collected data. In the event that language differences present a barrier to data collection, strategies to ensure proper collection will be employed, including seeking help from other team members, slowing down testing pace, or using translators if necessary.

Risks (as described in informed consent form):

The known or expected risks will be defined as: Likely - occurring in more than 25% of people (more than 25 out of 100 persons); Common – occurring in 10% - 25% of people (in 10 to 25 out of 100 persons); Infrequent - occurring in 1 - 10% of people (1 to 10 out of 100 people); Rare - occurring in less than 1% of people (fewer than 1 out of 100 persons); or Very Rare - occurring in less than 0.1% of people (fewer than 1 in 1,000 persons).

The known or expected risks will be described in normal script.

The actions that the researchers take to minimize these risks will be described in italic script, as demonstrated in this paragraph.

General risks:

There is a very rare risk of breach of confidentiality, which may affect privacy, self-esteem, social standing, employability, and insurability.

Section 9.1 will provide more detailed information on how we protect your privacy. In general, study records will be kept in databases maintained by the investigators. These databases are kept separate from medical records, are protected by passwords, and only accessible to personnel involved in the study. If you withdraw from the study at any time, a record of the withdrawal and the reasons given for withdrawing may be kept as part of the study record.

There is a rare risk that you may experience some minor anxiety ('test anxiety'), become worried, or have an anxiety reaction in response to any of these tests and procedures. For

example, you become worried about your health, or you may experience a sudden fear of the confined space while in the scanner.

Trained research staff will conduct all tests and procedures. The staff will be prepared to respond to your anxiety, concerns and behavioral changes, by temporarily suspending testing, breaking up testing sessions into several brief visits if needed, and/or answering your questions. During the MRI scans you will be able to talk to technologists throughout the scan and indicate right away if you wish to stop the study and leave the scanner. At the option of your personal physician, (s)he may prescribe sedation with lorazepam (Ativan) or diazepam (Valium) to be taken before the scan in accordance with the prescription directions.

None of the test results, including brain images, and procedures in this study will be reviewed or interpreted for making a medical diagnosis. Any result or abnormality that would be indicative of current or future disease will most likely not be discovered. However, if we do find a clinically relevant result or abnormality that deserves additional medical attention, we will communicate this to you and you will be urged to visit your primary health care provider. The research results of the brain images and genetic testing will NOT be communicated back to you.

You should consult your personal doctor if you have any health concerns

Clinical tests:

There is a very rare risk of physical fatigue during the clinical examination.

Trained research staff will conduct all the tests and administer all the questionnaires. The staff will be prepared to respond to your concerns by temporarily suspending testing and/or breaking up testing sessions into several brief visits if needed.

There is a common risk that you may have a dry mouth after providing the saliva sample.

You may drink some water after providing the sample.

Smell and vision tests:

There is a very rare risk of a mild allergic reaction to the scents of the smell identification test.

Testing will be discontinued if you experience an allergic reaction that prevents you from continuing the examination.

There is a very rare risk that you may experience some minor eye strain when doing the vision tests.

Rest breaks will be provided if needed. Any minor eye strain will disappear shortly after the test.

Motor testing:

Many of the tests are comparable to normal standing and walking conditions that you may experience in everyday-life. Nonetheless, there is an infrequent risk of falling or near-falling during these tests which may result in fall-related injuries.

Trained research staff will remain in close proximity to you at all times, and observe ('spot') you to prevent you from falling.

There is a very rare risk that the sensors to measure overall movement and balance may become detached and that you may trip. You may also trip on the pressure sensitive mat.

We will regularly check the sensors for appropriate attachment and you will be closely monitored.

Eye movements will be measured with video eye goggles (videonystagmography or VNG) while you are making small eye movements. There is rare risk that these protocols may cause some eye strain discomfort.

Rest breaks will be provided if needed. Any minor eye strain will disappear shortly after the test.

Muscle Testing:

There is a risk of pressure or muscle fatigue when using the handheld dynamometer and Biodex equipment.

Experienced personnel will assist in muscle testing and stop testing if discomfort occurs.

Neuropsychological and neurobehavioral tests:

There is an infrequent risk of boredom, frustration, and/or mental and physical fatigue during the neuropsychological and neurobehavioral testing.

Trained research staff will conduct all the tests and administer all the questionnaires.

The staff will be prepared to respond to your concerns by temporarily suspending testing and/or breaking up testing sessions into several brief visits if needed.

MRI scan:

There is a minor risk of discomfort or anxiety from being in the confined space of the MRI scanner.

We will provide pads and blankets to make you as comfortable as possible. You will be able to talk to us throughout the study, and you will be able let us know right away if you want to stop the study and get out of the scanner.

There is a rare risk of hearing damage or loss due to loud, vibrating noises generated by the MRI scanner.

You will be provided foam earplugs to reduce the loud noises made by the scanner and prevent any hearing damage.

Some studies, like this one, have the potential to cause "peripheral nerve stimulation" (PNS). PNS is a light touching sensation on the skin surface, lasting only for a few seconds. It may cause mild discomfort, but is not harmful to you.

The MRI machine is operated within FDA guidelines so the potential for inducing PNS is low.

Sometimes, subjects report a temporary, slight dizziness, light-headedness or nausea during or immediately after the scanning session.

If you feel dizzy or light-headed, we will have you get up slowly from the scanner.

Because the strong electromagnetic fields can move metal objects and cause heating, there is a risk that loose objects (jewelry, keys) outside your body could be accelerated by the magnetic field and strike you, causing you injury. There is also a risk that the magnetic fields could disturb a metal fragment in your body, interfere with an implanted device, such as a pacemaker or neurostimulator, or cause metal (including foil-backed medication patches) on or in your body to heat up, causing you harm.

We keep the environment around the MRI scanner completely free of loose metal objects that could be moved by the magnetic field, and we will make sure that you have no metal on your body that could be affected by the MRI scanner. We will also

ask you questions and have you complete an MRI screening form to make sure that you have no metal inside your body that would cause you harm during the MRI scan.

There is the potential that a magnetic resonance image may reveal an abnormality that is already in your body, such as a cyst or tumor. Many such abnormalities are not clinically significant, but you may need or want to investigate them further. Such a finding might require additional studies, and maybe even treatment, which would not be paid for by the investigators, the sponsor, or the University of Michigan.

PET scans:

There is an infrequent risk of bruising, bleeding, infection, or soreness associated with intravenous catheter placement, similar to the risks associated with routine blood testing. Also, you may feel dizzy or lightheaded or may rarely even faint when the tube is put in or taken out.

We will use highly trained personnel for placement and removal of the IV.

There is a very rare risk that you could experience an allergic reaction to the PET tracer. This could involve itching, skin rash or shortness of breath shortly after injection. However, because of the very small tracer amounts used in PET imaging, the risk is very rare.

A physician will be available and an emergency cart is located in the PET Facility for treatment of any adverse reactions that may occur.

During the course of this study, you may potentially be exposed to radiation from the DXA scan, the PET/CT transmission scans and the PET tracer [^{11}C]PE2I.

The biological effect of radiation in humans is measured in terms of Sieverts (Sv) or mSv (1/1000 Sv), which is a unit of uniform whole body exposure. Exposure to a single PE2I PET-CT scan is 3.8 mSv (which is slightly above the annual level of natural background radiation of about 3 mSv).

The maximum amount of radiation you will be exposed to from this research project will be approximately 3.81 mSv for the PE2I scan. In the event of a technical failure, one (1) of scan may be repeated, which would expose you to a maximum exposure of 7.62 mSv. In the case of re-recruitment of a prior participant who previously completed a brain PE2I PET-CT scan and will undergo a repeat brain PE2I PET-CT scan, the additional radiation exposure will be 3.81 mSv for a total of 7.62 mSv. Participants will not exceed 2 brain PE2I PET-CT scans per year for this study. The effects on the body of this radiation exposure will be added to your overall lifetime radiation risk. The US Federal Government requires that the annual amount of radiation exposure of radiation workers does not exceed 50 mSv per year; the maximum radiation you will be exposed is about 3/10th of this amount. Exposure to an (optional) DXA scan is less than 0.1% of annual background radiation exposure. Your lifetime radiation risk also includes any radiation you may have received in the past for diagnosis or treatment, and any such radiation you may be exposed to in the future. Please inform the investigators if you have had any major radiation exposure in the past, particularly in the past year, such as medical treatment with X-rays or radioactivity, or diagnostic X-rays, CT-scans or nuclear medicine scans. No PET scans will be performed on pregnant, nursing, or potentially pregnant women. A urine pregnancy test will be performed on all women of childbearing potential within 48 hours prior to the PET/DXA scanning session.

Genetic testing:

We will be testing for multiple genes that are related to clinical symptom presentation. There is a very rare risk that the genetic information we obtain from your samples could prove embarrassing to you, if somebody were able to link the genetic information with you.

We have a system of double-coding the genetic information, so that it is extremely unlikely that the genetic information would be connected with you. Most importantly, we will break the link between the genetic information and you once the study is completed, thus removing this risk entirely.

The federal Genetic Information Nondiscrimination Act (GINA) generally makes it illegal for health insurance companies, group health plans, and most employers to discriminate against you based on your genetic information. This law does not protect you against genetic discrimination by companies that sell life insurance, disability insurance, or long-term care insurance. Under this law:

- *Health insurance companies and group health plans may not request your genetic information that we obtain from this research*
- *Health insurance companies and group health plans may not use your genetic information when making decisions regarding your eligibility or premiums*
- *Employers with 15 or more employees may not use your genetic information that we obtain from this research when making a decision to hire, promote, or fire you or when setting the terms of your employment*

GINA does not apply to the following groups; however, these groups have policies in place that provide similar protections against discrimination:

- *Members of the US Military receiving care through Tricare*
- *Veterans receiving care through the Veteran's Administration (VA)*
- *The Indian Health Service*
- *Federal employees receiving care through the Federal Employees Health Benefits Plans*

Assessment of daily life activity:

There is a very rare risk of the movement monitor(s) (Actigraph or ActivPAL) detaching, which may result in a trip during the daily life monitoring of overall movement (actigraphy). It should be noted that the actigraphy only measures overall movement. Neither devices record your geographical location or specific activities that you were performing, neither can this be derived at a later point from the data that is stored in the Actigraph or ActivPAL.

You will receive instruction for proper attachment of the Actigraph and/or ActivPAL system.

C-L Dopa-specific risks:

There is a common risk of nausea and an infrequent risk of vomiting.

Participants are given the option to come into the lab for their first dosage of C-L Dopa. This optional visit would be 60-120 min in length where the participant will take their first dose of 25/100 C-L Dopa and be monitored by study personnel. The peak dosage time for C-L Dopa is 60-90 min, so if a participant is going to experience nausea or vomiting it would be in the first 60-90 min after taking a dose.

The Carbidopa Monotherapy is done to reduce the chance of nausea and vomiting before starting C-L Dopa. All participants will receive three days of carbidopa monotherapy as a pre-treatment and will stay on this dose during the C-L Dopa treatment period.

Participants will be informed to take medication 30 minutes before a meal with a piece of fruit and with fruit juice to reduce chances of nausea and vomiting. Also, participants will be informed to not take medication with or after a protein filled meal, because this will increase the chance of nausea.

There is an infrequent risk of sleepiness. There is a very rare risk of falling asleep without warning while taking C-L Dopa.

Participants are given the option to come into the lab for their first dosage of C-L Dopa. This optional visit would be 60-120 min in length where the participant will take their first dose of 25/100 C-L Dopa and be monitored by study personnel. If you experience any episodes of sudden sleep onset or excessive daytime sleepiness, please contact the study team immediately. Medication use may be suspended, and further action taken, including withdrawal from the study.

You understand that you should not operate machinery or drive until these symptoms have disappeared.

There is an infrequent risk orthostatic hypotension when taking C-L Dopa. Participants taking antihypertensive medications (e.g. Hydrochlorothiazide, Atenolol, etc.) may be at higher risk of experiencing symptoms such as dizziness or lightheadedness when standing up after sitting.

Participants are given the option to come into the lab for their first dosage of C-L Dopa. This optional visit would be 60-120 min in length where the participant will take their first dose of 25/100 C-L Dopa and be monitored by study personnel.

If these symptoms are experienced at home, please contact study team immediately. Medication use may be suspended, and further action taken, including withdrawal from study.

There is an infrequent risk of insomnia, anxiety, confusion, abnormal dreams, hallucination, psychosis, diarrhea, and constipation.

Participants are given the option to come into the lab for their first dosage of C-L Dopa. This optional visit would be 60-120 min in length where the participant will take their first dose of 25/100 C-L Dopa and be monitored by study personnel.

If these symptoms are experienced at home, please contact study team immediately. Medication use may be suspended, and further action taken, including withdrawal from study.

There is a common risk of dizziness and headache. There is a rare risk of chest pain, dystonia, urinary frequency, ischemia, back pain, muscle cramps, and shoulder pain.

Participants are given the option to come into the lab for their first dosage of C-L Dopa. This optional visit would be 60-120 min in length where the participant will take their first dose of 25/100 C-L Dopa and be monitored by study personnel.

Please lay down until symptoms pass.

If these symptoms are experienced at home, please contact study team immediately. Medication use may be suspended, and further action taken, including withdrawal from study.

There is a rare risk of psychological changes while taking C-L Dopa. These may include the development of depression/suicidal tendencies, libido changes, increased urges to gamble, spend money, or practice binge-eating.

Participants are given the option to come into the lab for their first dosage of C-L Dopa. This optional visit would be 60-120 min in length where the participant will take their first dose of 25/100 C-L Dopa and be monitored by study personnel. Monitoring will continue during the medication period in the form of weekly phone-call check ins.

If these symptoms are experienced at home, please contact study team immediately. Medication use may be suspended, and further action taken, including withdrawal from study.

Given the very low dose of C-L Dopa we do not anticipate any significant withdrawal symptoms when stopping the medication as this is not observed at the 25/100 TID PO dose in clinical practice. Please refer the package insert for a comprehensive list of potential side effects.

While taking the placebo, you will not be ingesting any active ingredient. Placebos are commonly used in research and some patients do report side effects. There is an **infrequent** risk of nausea and a **rare** risk of vomiting while taking a placebo medication. Additionally, there is an **infrequent** risk of drowsiness and a **rare** risk of allergic reactions, such as skin rashes to the placebo.

While we will not know if you are receiving a placebo or the active drug C-L Dopa, researchers will closely monitor all participants for side effects. All participants will be given the option to take the first dose in the lab, so the study team can help monitor reactions. Participants can take the medication 30 minutes before a meal with a piece of fruit or juice to reduce the chances of nausea and vomiting. If you experience any drowsiness, do not operate machinery or drive.

Biopsy Specific Risks:

There is a **rare** risk of an allergic reaction to local anesthesia.

Participants will be screened for any allergies to drugs to avoid the possibility of an allergic reaction. A physician will be administering the anesthesia and biopsy after receiving specialized training.

There is a **rare** risk of severe pain or nerve damage during the administration of the biopsy.

While receiving a biopsy typically causes temporary discomfort, severe pain is not anticipated. To prevent this, a local anesthesia will be used, and only trained research staff will be completing the biopsy visits. Biopsies are frequently performed in a clinical setting and are deemed safe. Research staff has been trained on the correct positioning and pressure to apply during the biopsy. The procedure itself will be performed by a clinician.

There is a **rare** risk of excessive bleeding after the biopsy procedure.

Participants will be screened for bleeding disorders and blood thinning medications. The biopsy will be performed by a clinician who can apply pressure

to the site of biopsy immediately following administration to stop any bleeding. Subjects will be instructed that they should report any bleeding or opening of the wound immediately for follow up care. Subjects will be supplied with ice and pressure bandages after each biopsy to reduce inflammation and any soreness after the biopsy. A member of the research team will follow-up with participants the day after each muscle biopsy.

There is an **infrequent** risk of wound infection after the biopsy.

Participants will be provided with bandages to keep the punch site dry and covered. Participants will be screened for infection risk factors such as immunocompromising conditions. Subjects will be instructed that they should report any bleeding or opening of the wound immediately for follow up care. Subjects will be supplied with ice and pressure bandages after each biopsy to reduce inflammation and any soreness after the biopsy. A member of the research team will follow-up with participants the day after each muscle biopsy.

There is a **rare** risk of a stress reaction occurring before, during, or following the biopsy for those uncomfortable with blood or the tools used during the procedure, or for those with a history of stress reactions.

This risk is possible for participants who experience a stress reaction in healthcare environments or with procedures involving tools such as needles. Stress reactions can include a hypertensive (elevated blood pressure) response, chest pains, headaches, or difficulty breathing. Subjects are informed what is involved in the biopsy procedure so they can decide on if they are comfortable completing the procedure. Additionally, trained study team members will monitor the participants throughout the biopsy to determine if a stress reaction is occurring. In the case of a reaction, the study team will monitor vitals, have the participant remain seated or lying down, and can provide water as needed. An on-site neurologist can also check on the patient if needed.

Blood draw specific risks:

There is an **infrequent** risk of bruising, bleeding, or soreness at the injection site. There is a **very rare** risk for infection. There is a **rare** risk that you may feel dizzy, lightheaded, or faint after the injection.

Blood drawing, iv catheter insertions, and injections will be performed by a certified and experienced research technician or other health care professional who is also trained in blood borne pathogens control. Aseptic techniques will be used in accordance with University of Michigan guidelines. You can lie down if you feel dizzy, lightheaded or faint after an injection.

Open-label study: Subject compensation (as described in informed consent form):

You will receive \$50 for each completed MRI scan. You will receive \$50 for each completed PE21 PET scan. Payment for completion of the detailed clinical baseline test day will be \$100 and \$100 for follow-up. You will also receive \$50 for completing the limited clinical test day and medication phase of the study. Compensation for your time and effort after full study completion may total a maximum of \$500.

Overnight accommodations may be provided depending on personal circumstances or if you live far away. We will discuss with you the need for these accommodations as the research appointment(s) are being arranged. If eligible, overnight lodging can be arranged through the UMHS Patient and Visitor Accommodations Program either by a study team member or by you. However, you may decide to make alternative arrangements. In that case, please discuss with the study team first if you are eligible for reimbursement prior to making any reservations. We can only reimburse for expenses that have been approved in advance by the study team. You will need to provide receipts to the study team before expenses can be reimbursed. You will receive a voucher for valet parking at the University Hospital. Parking at Domino's Farms is free.

You will be paid after your last study visit or, in case you decide to withdraw from the study, you will be paid for the parts that you have completed. You will be paid by check, which will be sent to your home address. Alternatively, you may request a payment coupon for cash payment at the University Hospital. We do not keep cash for immediate payment.

If you receive payment of \$600 or more for taking part in this study, the University of Michigan accounting department will collect your name, address, social security number, payment amount, and related information. For tax reporting purposes this information must be sent to the Internal Revenue Service (IRS).

Placebo-controlled study (sub-study 1): Subject compensation (as described in informed consent form):

You will receive \$50 for a completed MRI scan. You will receive \$75 for a completed PE21 PET scan. Payment for completion of the detailed clinical baseline test day will be \$30 (\$10 for screening, \$20 for remaining tests). and \$30 for follow-up. You will also receive \$15 for completing the limited clinical test day and medication phase of the study. You will receive \$40 for completion of the optional skin biopsy. Compensation for your time and effort after full study completion may total a maximum of \$240. You will receive a voucher for valet parking at the University Hospital. Parking at Domino's Farms is free. Participants who are consented and then deemed ineligible following the screening will be compensated the \$10 for the screening visit.

You will be paid after your last study visit or, in case you decide to withdraw from the study, you will be paid for the parts that you have completed. You will be paid by check, which will be sent to your home address. Alternatively, you may request a payment coupon for cash payment at the University Hospital. We do not keep cash for immediate payment.

If you receive payment of \$600 or more for taking part in this study, the University of Michigan accounting department will collect your name, address, social security number, payment amount, and related information. For tax reporting purposes this information must be sent to the Internal Revenue Service (IRS).

Exploratory Muscle Testing Study (sub-study 2): Subject compensation (as described in informed consent form)

You will receive \$50 for a completed MRI scan. You will receive \$75 for a completed PE21 PET scan. Payment for completion of the detailed clinical baseline test day will be \$30 (\$10 for screening, \$20 for remaining tests). and \$30 for follow-up. You will also receive \$15 for completing the limited clinical test day and medication phase of the study. You will receive \$50 for each completed muscle biopsy and \$25 for each completed blood draw. Compensation for your time and effort after full study completion may total a maximum of

\$350. You will receive a voucher for valet parking at the University Hospital. Parking at Domino's Farms is free. Participants who are consented and then deemed ineligible following the screening will be compensated the \$10 for the screening visit.

You will be paid after your last study visit or, in case you decide to withdraw from the study, you will be paid for the parts that you have completed. You will be paid by check, which will be sent to your home address. Alternatively, you may request a payment coupon for cash payment at the University Hospital. We do not keep cash for immediate payment.

If you receive payment of \$600 or more for taking part in this study, the University of Michigan accounting department will collect your name, address, social security number, payment amount, and related information. For tax reporting purposes this information must be sent to the Internal Revenue Service (IRS).

your name, address, social security number, payment amount, and related information. For tax reporting purposes this information must be sent to the Internal Revenue Service (IRS).

Remote consent and remote assessments:

Data may be collected remotely (using Zoom for Health at U of M) or telephone call if feasible for assessment. Remote electronic consent may be obtained using SignNow, this is being done to reduce physical interactions between subjects and study staff.
