Version 2.0

07/16/2021

Preface

The VHA predictive model identifies the top 5% of VHA patients at the highest predicted risk for suicide. These Veterans identified by VHA accounted for approximately 24% of all the suicide deaths, 37% of all reported suicide attempts, and 31% of inpatient psychiatric hospitalizations observed in VHA over the course of one year. Veterans in the highest 0.01% of the risk stratum had suicide rates 82 times greater than the rest of the sample in a development model.

Using this predictive model, VHA's Office of Mental Health and Suicide Prevention implemented a national suicide prevention outreach program entitled Recovery Engagement and Coordination for Health – Veterans Enhanced Treatment (REACH VET). REACH VET utilizes a dashboard to provide the names of patients identified by the model monthly to coordinators at each VA medical facility. REACH VET coordinators are responsible for notifying providers of the patient's status and prompting providers to re-evaluate care and take appropriate clinical steps if they are not already occurring (e.g., contacting the patient to re-engage in care, discussing potential changes in care with the patient).

Implementation assistance in the form of virtual external facilitation, an evidence-based implementation strategy, was offered to sites having difficulty implementing REACH VET during the system-wide rollout of the program. The analysis plan for specific aim 1b is below.

Scope and Analysis

Low performing VHA facilities were identified by leadership in seven Veteran Integrated Service Networks (VISN). Implementation assistance in the form of virtual external facilitation, an evidence-based implementation strategy, was offered to sites having using a stepped wedge design clustering sites at the VISN level. Two VISNs no longer needed facilitation by the time they reached the opportunity to receive it; these VISNs and facilities were excluded from any analyses. REACH VET Historic Summary Reports contain summary metrics used to evaluate facility performance on the four measures listed below.

REACH VET Outcome Measures

- Coordinator Assigned – the percentage of eligible Veterans who had a Coordinator assigned within a week of the monthly REACH VET scores being released. The denominator is the number of eligible Veterans within that week. The numerator is the number of Veterans with a record of a Coordinator assigned within or prior to that week.
- Provider Assigned – the percentage of eligible Veterans who had a Provider assigned within a week of the monthly REACH VET scores being released. The denominator is the number of eligible Veterans within that week. The numerator is the number of Veterans with a record of a Provider assigned within or prior to that week.

- Care Evaluation Performed – the percentage of eligible Veterans who had a care evaluation performed within a week of the monthly REACH VET scores being released. The denominator is the number of eligible Veterans within that week. The numerator is the number of Veterans with a record of a care evaluation performed within or prior to that week.
- Attempted Outreach – the percentage of eligible Veterans with a recorded attempted outreach within a week of the monthly REACH VET scores being released. The denominator is the number of eligible Veterans within that week. The numerator is the number of Veterans with a recorded attempted outreach within or prior to that week.

All outcomes data was collected from the Week 2 view of the REACH VET Historic Summary Report and encompasses days 1-14 after the release date.

Design Methods

Initial analysis design prescribed a stepped-wedge model clustering sites at the VISN level as depicted in figure 1.

| | Months | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------------------|--------|---|---|---|---|---|---|---|---|----|----|--------------------|----|---------------------|----|----|----|----|----|----|----|----|----|----|----|--|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | |
| Cluster A - 5 Sites | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Cluster B - 4 Sites | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Cluster C - 4 Sites | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Cluster D - 6 Sites | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Cluster E - 4 Sites | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | | | | | | | | | | | Pre-Implementation | | | | | | | | | | | | | | |
| | | | | | | | | | | | | | | Post-Implementation | | | | | | | | | | | | |

Figure 1. Study design assuming stepped wedge method at VISN level.

After initial sensitivity analysis (see section on Model fitting) it was determined that clustering at the VISN level lacked sufficient sample size compared to the quasi-experimental pre-post design as represented in figure 2.

Figure 2. Study design timeline assuming clustering within site.

Model Fitting

Pan (2001) proposed a quaslikelihood model-selection method for GEE under the independence model criterion (QIC). This criterion can also be used to select the best working correlation structure in GEE analyses (Cui, 2007).

Stepped Wedge within *CLUSTERS* QIC Scores

| Outcome | Independent | Autoregressive | Compound Symmetry | Unstructured |
|---------------------------|-------------|----------------|-------------------|--------------|
| Coordinator Accepted | 59.0 | 60.0 | 69.2 | NC |
| Provider Assigned | 86.0 | 86.3 | 92.6 | 36.6 * |
| Care Evaluation Performed | 89.8 | 89.7 | 93.5 | 45.1 |
| Outreach Attempted | 95.3 | 95.5 | 126.8 | NC |

NC – non-convergence, * Unstructured matrix is predominately negative on the pairs

Stepped Wedge within *SITES* QIC Scores

| Outcome | Independent | Autoregressive | Compound Symmetry | Unstructured |
|----------------------|-------------|----------------|-------------------|--------------|
| Coordinator Accepted | 57.3 | 56.9 | 60.07 | CE |

| | | | | |
|---------------------------|-------|-------|-------|----|
| Provider Assigned | 97.1 | 92.0 | 109.2 | CE |
| Care Evaluation Performed | 109.0 | 102.8 | 116.6 | CE |
| Outreach Attempted | 116.9 | 107.8 | 119.8 | CE |

CE – converged with error

6-month Pre-Post within SITES QIC Scores

| Outcome | Independent | Autoregressive | Compound Symmetry | Unstructured |
|---------------------------|-------------|----------------|-------------------|--------------|
| Coordinator Accepted | 38.2 | 38.6 | 37.5 | NC |
| Provider Assigned | 73.0 | 66.5 | 57.0 | NC |
| Care Evaluation Performed | 80.7 | 73.0 | 71.8 | NC |
| Outreach Attempted | 87.2 | 81.3 | 81.6 | NC |

Choose 6-month pre-post quasi-experimental model using compound symmetry correlation structure for observations within sites, time variable in months to account for secular trends, and a binary intervention variable (0,1) indicating study phase (pre-facilitation, post-facilitation).

Note, we do not model a transition period from pre-to-post Average number of implementation days = 175 (SD 49.3). Index date is based upon date of site visit.

Analysis

Our quasi-experimental pre-post intervention analysis evaluated four outcome measures as tracked by the REACH VET program across 23 VAMCs, during 6-month periods prior to implementation and again after the onset of implementation. We used the REACH VET Historic Summary Report to collect metrics for Coordinator assignment, Provider assignment, Care evaluation, and Attempted outreach all within one week of each monthly report's release date. To compare statistical differences in outcomes between pre-and post-periods we used generalized estimating equations (GEE) to control for clustering of observations within VAMCs. Fixed effects included a time-dependent variable identifying change in intervention status (pre-post) as well an independent variable of time to account for the possibility of improvement due to secular trends.
