

Fluoroethyltyrosine for the evaluation of intracranial neoplasm (UC-GlioFET)

Protocol Number: CC #171022

Study Drug: Fluoroethyltyrosine (FET)

Version Number: Version 2.1

Version Date: 08/28/2025

IND Number: 138930

Principal Investigator (Sponsor-Investigator)

Javier Villanueva-Meyer, MD (neuroradiology)
Associate Professor, Radiology
University of California, San Francisco

Thomas Hope, MD (nuclear medicine)
Professor, Radiology
University of California, San Francisco

Abstract

| | |
|----------------------|---|
| Title | Fluoroethyltyrosine (FET) for the evaluation of intracranial neoplasm (UC-GlioFET) |
| Patient population | <p>Patient population 1: Patients with intracranial neoplasms (glial or metastatic disease) with concern for recurrence or progression on conventional imaging (e.g., MRI). Three sub-populations will be considered:</p> <ol style="list-style-type: none"> 1. Recurrent metastatic lesions 2. Recurrent high-grade gliomas (Grades 3 and 4) 3. Recurrent low-grade gliomas (Grades 1 and 2) <p>Patient population 2: Patients with suspected glial neoplasms (Grade 2-4) planning to undergo biopsy or surgery prior to primary treatment (radiation therapy and/or surgery)</p> |
| Rationale for Study | FET accumulates in malignant cells within intracranial neoplasms and can be used to detect recurrent disease and characterize grade of glial neoplasms. |
| Primary Objective | To determine if FET PET can differentiate between benign treatment-related changes (TRC) and recurrent glioma in comparison to a composite standard of truth (CSOT) that includes pathology and other clinical information, evaluated using estimates of sensitivity and specificity. |
| Secondary Objectives | <ol style="list-style-type: none"> 1) To determine if FET PET can differentiate between benign TRC and recurrent glioma in comparison to a histopathological standard of truth. 2) To determine if FET PET can differentiate between benign TRC and recurrent glioma in comparison to a CSOT evaluated using estimates other than subject-based sensitivity and specificity. 3) To assess the safety of FET PET, as determined by treatment emergent adverse events (TEAEs) within 48 hours of FET administration. 4) To describe the inter-reader variability between 3 independent blinded readers of FET PET images in their assessments of benign TRC versus recurrent glioma. 5) To describe intra-reader variability between 3 independent blinded readers of FET PET images in their assessments of benign TRC versus recurrent glioma. |

| | |
|------------------------|--|
| Exploratory Objectives | <ol style="list-style-type: none"> 1) To assess relationships between serial FET PET and clinical outcome (benign TRC and recurrence) in patients with recurrent metastatic lesions, recurrent high grade gliomas and recurrent low grade gliomas. 2) To determine if MRI can differentiate between benign treatment-related changes and recurrence. 3) To describe the distribution of the standardized uptake value (SUV) and tumor-to-background ratio (TBR) for observed lesions. 4) To determine if FET PET can differentiate between benign TRC and recurrent metastatic lesions. 5) To determine if FET PET can accurately differentiate between low-grade and high-grade gliomas in population 2. |
| Study Design | This is a prospective, Phase 2, single center, open-label study in patients with intracranial neoplasms. There is a provision of Stopping Rules for the Pediatric patient population. |
| Number of patients | 199 patients, enrolled over four years. 150 patients will be enrolled in patient population 1 and 49 patients will be enrolled in patient population 2. |
| Primary Endpoints | <ol style="list-style-type: none"> 1) Sensitivity of FET PET using a CSOT (subject-level) 2) Specificity of FET PET using a CSOT (subject-level) |
| Duration of Therapy | The study will involve one imaging study involving FET PET for all patients. Adult patients may undergo repeat FET PET. |
| Duration of Follow up | Follow-up will be performed to correlate imaging findings with pathology. |
| Duration of study | The study will reach completion one year after completion of enrollment. |
| Study Drugs | Fluoroethyltyrosine (FET) |
| Safety Assessments | Patient vital signs will be taken immediately before and after the administration of the radiopharmaceutical. The patients will also be asked to report adverse events. |

1 Introduction

1.1 Overview

Imaging using the amino acid-based PET tracer O-(2-[¹⁸F]fluoroethyl)-L-tyrosine (FET) is a promising imaging platform for both primary and secondary brain neoplasms. However, widespread incorporation of FET PET into the routine clinical management of brain tumor patients has not occurred within the United States. The primary issue associated with this promising imaging agent is the lack of approval by the Food and Drug Administration (FDA). The goal of this protocol is to obtain prospective data and the safety and efficacy of FET for the detection of intracranial neoplasms with the goal to submit a New Drug Application (NDA) for this agent. To date we are not aware of an institution on the United States who has previously obtained an IND for FDA or submitted an FDA application. We are aiming to achieve two indications with this study. The first is the ability to accurately detect recurrent disease in patients who have previously undergone surgery and/or radiation. The second indication is the ability to distinguish low-grade glial neoplasms from high-grade glial neoplasms.

1.2 Background

Glial tumors are the most common primary neoplasms affecting the central nervous system. This heterogeneous group of tumors is classified as low or high grade based on histologic features such as the presence of increased cellularity, mitotic activity or necrosis (1). Due to their infiltrative nature, gliomas are rarely cured via surgical resection, contributing to a disproportionately high morbidity and mortality (2,3).

Imaging techniques play an important role in the clinical management of neuro-oncology patients. Anatomic imaging with magnetic resonance imaging (MRI) is the mainstay for initial diagnosis, treatment planning and post-treatment follow-up of brain tumors given its widespread availability, high spatial resolution and excellent soft tissue contrast. However, conventional MRI techniques have several important limitations in brain tumor imaging, including those currently used to define disease progression as part of the RANO criteria (Response Assessment in Neuro-Oncology) (4). Contrast enhancement, a marker of blood-brain barrier permeation, is neither sensitive nor specific for the presence of tumor tissue. The majority of low-grade glial neoplasms do not enhance, while inflammatory processes common in the postsurgical/post treatment setting often enhance avidly. A diagnostic dilemma occurs in up to 30% of patients within the first 12 weeks following completion of chemoradiotherapy, whereby an enlarging area of contrast enhancement on MRI may represent either early tumor progression, which necessitates a change in the ongoing treatment regimen, versus “pseudoprogression”, which represents non-progressive treatment-related change (TRC) that does not require alteration of the treatment regimen.

Positron-emission tomography (PET), which has the capability to image specific metabolic processes using radiolabeled endogenous molecules, is another imaging modality with high potential for use in neuro-oncology. The most widely used PET tracer is the glucose analogue fluorodeoxyglucose (FDG). However, FDG is not ideal for brain tumor imaging given the high background uptake of normal brain parenchyma and limited specificity in distinguishing between progressive tumor and post-treatment inflammation. O-(2-[¹⁸F]fluoroethyl)-L-tyrosine (FET) is an amino acid-based PET tracer with high uptake in brain tumors and relatively low uptake in normal brain parenchyma (5). Various studies have demonstrated the ability of FET PET to detect recurrent gliomas with higher sensitivity and specificity compared with conventional imaging techniques (6,7). Additionally, the value of using FET PET tumor grading has also been shown (8).

We believe that FET PET has significant promise in the imaging and characterization of patients with primary and secondary intra-cranial neoplasms. This protocol is intended to focus on the two main applications of the radiotracer in order to obtain the data required for the submission of an NDA application from the FDA.

Of note, we will follow-up patients without histologic correlation in order to determine the accuracy of imaging follow-up as a possible replacement for histology as a marker of disease recurrence. This will be the motivation and goal of the study's primary objective.

1.3 Patient Population

Patient population 1: Patients with intracranial neoplasms (glial or metastatic disease) with concern for recurrence or progression on conventional imaging (e.g., MRI). This population will be broken into three groups:

1. Recurrent metastatic lesions
2. Recurrent high-grade gliomas (Grades 3 and 4)
3. Recurrent low-grade gliomas (Grades 1 and 2)

Patient population 2: Patients with suspected glial neoplasms (Grade 2-4) planning to undergo biopsy or surgery prior to primary treatment (radiation therapy and/or surgery).

2 Objectives of the Study

2.1 Primary Objective

| Primary Objective | Endpoints | Time Frame |
|--|---|-----------------|
| 1. To determine if FET PET can differentiate between benign treatment-related changes (TRC) and recurrent glioma in comparison to a composite standard of truth (CSOT) that includes pathology and other clinical information, evaluated using estimates of sensitivity and specificity. | <ul style="list-style-type: none">• Sensitivity of FET PET using a CSOT (subject-level)• Specificity of FET PET using a CSOT (subject-level) | Up to 6 months. |

2.2 Secondary Objectives

| Secondary Objectives | Endpoints | Time Frame |
|--|---|-----------------|
| 1. To determine if FET PET can differentiate between benign TRC and recurrent glioma in comparison to a histopathological standard of truth. | <ul style="list-style-type: none"> • Sensitivity of FET PET using a histopathology standard of truth (subject- and lesion-level) • Specificity of FET PET using a histopathology standard of truth (subject and lesion-level) • Positive Predictive Value (PPV) of FET PET using a histopathology standard of truth (subject and lesion-level) • Negative Predictive Value (NPV) of FET PET using a histopathology standard of truth (subject and lesion-level) • Accuracy of FET PET using a histopathology standard of truth (subject and lesion-level) • Misclassification Rate of FET PET using a histopathology standard of truth (subject and lesion-level) | Up to 6 months. |
| 2. To determine if FET PET can differentiate between benign TRC and recurrent glioma in comparison to a CSOT evaluated using estimates other than subject-based sensitivity and specificity. | <ul style="list-style-type: none"> • Sensitivity of FET PET using a CSOT (lesion-level) • Specificity of FET PET using a CSOT (lesion-level) • PPV of FET PET using a CSOT (subject and lesion-level) • NPV of FET PET using a CSOT (subject and lesion-level) • Accuracy of FET PET using a CSOT (subject and lesion-level) • Misclassification Rate of FET PET using a CSOT (subject and lesion-level) | Up to 6 months. |

| Secondary Objectives | Endpoints | Time Frame |
|---|--|-----------------|
| 3. To assess the safety of FET PET, as determined by treatment emergent adverse events (TEAEs) within 48 hours of FET administration. | Incidence of treatment-emergent adverse events (TEAEs) | Up to 48 hours. |
| 4. To describe the inter-reader variability between 3 independent blinded readers of FET PET images in their assessments of benign TRC versus recurrent glioma. | Fleiss' kappa | N/A |
| 5. To describe intra-reader variability between 3 independent blinded readers of FET PET images in their assessments of benign TRC versus recurrent glioma. | Cohen's kappa | N/A |

2.3 Exploratory Objectives

| Exploratory Objectives |
|---|
| 1. To assess relationships between serial FET PET and clinical outcome (benign TRC and recurrence) in patients with recurrent metastatic lesions, recurrent high grade gliomas and recurrent low grade gliomas. |
| 2. To determine if MRI can differentiate between benign treatment- related changes and recurrence. |
| 3. To describe the distribution of the standardized uptake value (SUV) and tumor-to-background ratio (TBR) for observed lesions. |
| 4. To determine if FET PET can differentiate between benign TRC and recurrent metastatic lesions. |
| 5. To determine if FET PET can accurately differentiate between low-grade and high-grade gliomas in population 2. |

3 Study Design

3.1 Characteristics

This is a prospective, Phase 2, single center, open-label study in patients with intracranial neoplasms. Eligible participants will undergo baseline assessments at enrollment. All study participants will undergo a single FET PET study. Repeat FET PET will be offered to adult patients and not in pediatric patients.

3.2 Stopping Rules

For pediatric patients, patients will be reviewed after imaging, and if inappropriate patient management is instituted based upon the results of the 18F-FET PET imaging, then we will suspend enrollment of pediatric patients until the case is reviewed with the FDA and the neurooncology site committee.

3.3 Number of Subjects

It is anticipated that 199 patients over four years will be enrolled in this study.

3.4 Eligibility Criteria

Patients must have baseline evaluations performed prior to the administration of the radiopharmaceutical and must meet all inclusion and exclusion criteria. In addition, the patient must be thoroughly informed about all aspects of the study, including the study visit schedule and required evaluations and all regulatory requirements for informed consent. The written informed consent must be obtained from the patient prior to enrollment. The following criteria apply to all patients enrolled onto the study unless otherwise specified.

Patients participating in other clinical trials will be eligible for this study including patients undergoing surgery guided by 5-aminolevulinic acid.

3.4.1 Inclusion Criteria

1. Presence or suspicion of intracranial neoplasm in two populations:
 - a. Population 1: patients after primary treatment (radiation therapy and/or surgery) with suspicion of recurrence on MRI. Three sub-populations will be considered:
 - i. Recurrent metastatic lesions
 - ii. Recurrent high-grade gliomas (Grades 3 and 4)
 - iii. Recurrent low-grade gliomas (Grades 1 and 2)
 - b. Population 2: patients prior to primary treatment with planned biopsy or surgical resection.
2. Age > 3 years.

3.4.2 Exclusion Criteria

1. Patient with known incompatibility to PET or CT/MRI scans.
2. Patient unlikely to comply with study procedures, restrictions and requirements and judged by the Investigator to be unsuitable for study participation.

- a. Sedation or anesthesia can be used for patients who cannot tolerate the exam.

3.5 Discontinuation of Study Intervention

Study drug will be given per protocol, unless any of the following discontinuation criteria are met:

- Unacceptable adverse event(s);
- Participant decides to discontinue study drug (with or without concurrent withdrawal of informed consent);
- Significant participant non-compliance with protocol;
- If the participant meets an exclusion criterion (either newly developed or not previously; or, recognized) that precludes further study drug administration.
- General or specific changes in the participant's condition render the participant unacceptable for study drug administration in the judgment of the investigator.

Participants will be discontinued from study drug administration when any of these criteria apply. The reason for discontinuation, and the date the participant discontinued (defined as the later date of decision to discontinue drug or last dose) must be documented in the case report form (CRF). Participants removed from study for unacceptable adverse events will be followed as described in Section 7.3. Participants who do not receive study drug will be replaced.

3.6 Duration of Follow Up

Patients will be in follow-up until their planned biopsy or surgery is performed to correlate imaging findings with histology. Follow-up will be performed off study, and there are no study specific related procedures that are required after the imaging study. If patients do not undergo biopsy or surgery, we will review imaging that was performed as clinical standard of care to determine if the lesion has grown as part of the secondary aims.

3.7 Study Discontinuation/Withdrawal

Participants will be discontinued/withdrawn from study participation when any of the following criteria apply:

- Completion of study intervention and follow-up per protocol
- Lost to follow-up
- Withdrawal of consent for data submission
- Death
- Study termination

The reason for discontinuing study participation and the off-study date must be documented in the case report form (CRF).

Participants may withdraw from the study at any time and for any reason at their own request or at the request of their legally acceptable representative. Participants will be asked for reason(s) of withdrawal and presence of any AEs for documentation in the CRF. If possible, the participant will be seen and assessed by the Investigator and AEs followed according to protocol.

The study may be terminated early for any reason, which may include, but is not limited to:

- Changes in the benefit-risk assessment
- Decision to stop manufacturing study drug

In the event of early study termination, follow up medical records collection may occur, as described in Section 3.6, for participants who remain on study at that time. Investigators will be notified of any additional steps that are necessary to protect participants' interests. Investigators must notify the IRB and other applicable stakeholders, in accordance with local laws and regulations.

3.8 Study Timeline

3.8.1 Primary Completion

The study will reach primary completion 48 months from the time the study opens to accrual.

3.8.2 Study Completion

The study will reach study completion 60 months from the time the study opens to accrual.

4 Study Drugs

4.1 Description, Supply and Storage of Investigational Products

4.1.1 Investigational Drug #1

O-(2-[¹⁸F]fluoroethyl)-L-tyrosine (FET) is a radiopharmaceutical that will be produced under cGMP by a research pharmacist certified and highly experienced in the Department of Radiology and Biomedical Engineering.

5 Treatment Plan

5.1 Patient Preparation

Patients will fast for four hours prior to examination as per joint EANM/EANO/RANO practice guidelines/SNMMI procedure standards for imaging of gliomas using PET with radiolabeled amino acids.

5.2 Dosage and Administration

The imaging agent (FET) will be administered on an outpatient basis. It will be administered intravenously within the PET scanner at the time of imaging. The nominal injected dose will be 4 to 7 mCi \pm 10% of FET per imaging time point. Pediatric doses will be adjusted based upon the patient's weight (dose = [(patient weight in kg)/70 kg] x adult dose). The maximum dose will be 7 mCi, adjusted by weight.

5.2.1 Other Modalities or Procedures

5.2.1.1 PET Imaging

Participants may undergo sedation as required in order to successfully undergo imaging. Sedation or anesthesia will be administered per institutional protocol.

Study participants will undergo the FET PET imaging after all screening and baseline assessments have been completed. The radiopharmaceutical will be administered while the

patient is in the PET scanner, and imaging will last for 40 minutes. Acquired PET data will be reconstructed so that three time points are created:

1. Perfusion: 60-second acquisition that starts immediately when activity is noted in the field of view.
2. Equilibrium: 10-minute acquisition acquired between 10 and 20 minutes after injection.
3. Washout: 10-minute acquisition acquired between 30 and 40 minutes after injection.

Additionally, a 20 minute acquisition will be reconstructed between 20 and 40 minutes after injection to match the analysis performed in Lohmann et al (8).

Each study will be reviewed by a board-certified nuclear medicine physician and neuroradiologist within seven working days of the completion of the study, and a formal report will be dictated. This will be performed separately from the final analysis. The imaging findings on FET PET will be provided to the neurosurgeon and can be used in addition to MRI for planning of biopsy and surgery. For patients who received subsequent surgery, if possible the multi-parametric imaging examination will be used to target 1-4 tissue samples that have distinct metabolic findings for distinguishing recurrent disease from treatment effects.

If imaging is performed on a PET/MRI, a gadolinium-based contrast will be administered. The patient's eGFR will be checked and gadolinium will be administered per radiology department guidelines. The MRI protocol will include the clinical standard MRI. The MRI protocol may also contain research sequences such as novel sequences used for attenuation correction on PET/MRI (ie ZTE or zero echo time) and MRI spectroscopy sequences.

Optional repeat FET PET imaging will be offered to adult patients.

5.3 Monitoring and Toxicity Management

Each patient receiving FET will be evaluable for safety. The safety parameters include vital signs (heart rate and blood pressure) as well as physical findings and spontaneous reports of adverse events reported to the investigator by patients.

6 Study Procedures and Observations

Screening assessments must be performed within 30 days prior to the first dose of investigational product. Any results falling outside of the reference ranges may be repeated at the discretion of the investigator. Treatment or visit delays for public holidays or weather conditions do not constitute a protocol violation.

A written, signed, informed consent form (ICF) and a Health Insurance Portability and Accountability Act (HIPAA) authorization must be obtained before any study-specific assessments are initiated. A copy of the signed ICF will be given to the subject and a copy will be filed in the medical record. The original will be kept on file with the study records.

REDCap will be used to collect data for this study. REDCap is a secure, HIPAA-compliant, web-based system.

6.1.1 Treatment Period

- FET administration and adverse event evaluation
 - Evaluation of adverse events 20 min after completion of imaging, \pm 60 min

- Vital signs
 - 20 min prior to administration of radiotracer, \pm 60 min
 - 20 min after completion of imaging, \pm 60 min
- Confirmation of negative pregnancy test (woman of childbearing potential only)

6.1.2 Follow-up

Patients will be followed up clinically to see if they have undergone biopsy or surgical resection. This will be performed based on standard of care and is not a requirement as part of this protocol. For patients who have not had biopsy or surgical resection, we will review imaging studies performed within six months of the FET PET in order to evaluate change in size as part of the secondary aims.

6.1.3 Optional Study Procedures - Imaging

Optional repeat FET PET imaging will be offered to adult patients. Repeat procedures include:

- FET administration and adverse event evaluation
 - Evaluation of adverse events 20 min after completion of imaging, \pm 60 min

6.2 Prohibited Medications

There are no prohibited medications.

7 Evaluation of Safety

7.1 Definitions

7.1.1 Evaluable for Toxicity

All patients will be evaluable for toxicity from the time of FET administration.

7.1.2 Adverse Event

An adverse event (also known as an adverse experience) is defined as any untoward medical occurrence associated with the use of a drug in humans, whether or not considered drug related. More specifically, an adverse event (can be any unfavorable and unintended sign (e.g., an abnormal laboratory finding), symptom, or disease temporally associated with the use of a drug, without any judgment about causality. An adverse event can arise from any use of the drug (e.g., off-label use, use in combination with another drug) and from any route of administration, formulation, or dose, including an overdose.

7.1.3 Adverse reaction

An adverse reaction is defined as any adverse event caused by the use of a drug. Adverse reactions are a subset of all suspected adverse reactions for which there is reason to conclude that the drug caused the event.

7.1.4 Suspected

A suspected adverse reaction is defined as any adverse event for which there is a reasonable possibility that the drug caused the adverse event. For the purposes of IND safety reporting,

“reasonable possibility” indicates that there is evidence to suggest a causal relationship between the drug and the adverse event. A suspected adverse reaction implies a lesser degree of certainty about causality than an adverse reaction.

7.1.5 Unexpected

An adverse event or suspected adverse reaction is considered unexpected if it is not listed in the investigator brochure or package insert(s), or is not listed at the specificity or severity that has been observed, or, if an investigator brochure is not required or available, is not consistent with the risk information described in the general investigational plan or elsewhere in the current application.

“Unexpected,” as used in this definition, also refers to adverse events or suspected adverse reactions that are mentioned in the investigator brochure as occurring with a class of drugs or as anticipated from the pharmacological properties of the drug, but are not specifically mentioned as occurring with the particular drug under investigation.

Adverse events that would be anticipated to occur as part of the disease process are considered unexpected for the purposes of reporting because they would not be listed in the investigator brochure. For example, a certain number of non-acute deaths in a cancer trial would be anticipated as an outcome of the underlying disease, but such deaths would generally not be listed as a suspected adverse reaction in the investigator brochure.

7.1.6 Serious

An adverse event or suspected adverse reaction is considered serious if, in the view of either the investigator or sponsor, it results in any of the following outcomes:

- Death
- Life-threatening adverse event
- Inpatient hospitalization or prolongation of existing hospitalization
- A persistent or significant incapacity or substantial disruption of the ability to conduct normal life function
- Congenital anomaly/birth defect

Important medical events that may not result in death, are life-threatening, or require hospitalization may be considered serious when, based upon appropriate medical judgment, they may jeopardize the patient or subject and may require medical or surgical intervention to prevent one of the outcomes listed in this definition. Examples of such medical events include allergic bronchospasm requiring intensive treatment in an emergency room or at home, blood dyscrasias or convulsions that do not result in inpatient hospitalization, or the development of drug dependency or drug abuse.

7.1.7 Life-threatening

An adverse event or suspected adverse reaction is considered life-threatening if, in the view of either the investigator or sponsor, its occurrence places the patient or subject at immediate risk of death. It does not include an adverse event or suspected adverse reaction that, had it occurred in a more severe form, might have caused death.

7.2 Recording of an Adverse Event

All grade 3 and above adverse events will be recorded using the NCI CTCAE v4.0. The Investigator will assign attribution of the possible association of the event with use of the investigational drug.

| Relationship | Attribution | Description |
|--|-------------|--|
| Unrelated to investigational drug/intervention | Unrelated | The AE <i>is clearly NOT related</i> to the intervention |
| | Unlikely | The AE <i>is doubtfully related</i> to the intervention |
| Related to investigational drug/intervention | Possible | The AE <i>may be related</i> to the intervention |
| | Probable | The AE <i>is likely related</i> to the intervention |
| | Definite | The AE <i>is clearly related</i> to the intervention |

Signs or symptoms reported as adverse events will be graded and recorded by the Investigator according to the CTCAE. When specific adverse events are not listed in the CTCAE they will be graded by the Investigator as none, mild, moderate or severe according to the following grades and definitions:

| | |
|----------|---|
| Grade 0 | No AE (or within normal limits) |
| Grade 1 | Mild; asymptomatic or mild symptoms; clinical or diagnostic observations only; intervention not indicated |
| Grade 2 | Moderate; minimal, local, or noninvasive intervention (e.g., packing, cautery) indicated; limiting age-appropriate instrumental activities of daily living (ADL) |
| Grade 3: | Severe or medically significant but not immediately life-threatening; hospitalization or prolongation of hospitalization indicated; disabling; limiting self-care ADL |
| Grade 4: | Life-threatening consequences; urgent intervention indicated |
| Grade 5: | Death related to AE |

7.3 Follow-up of Adverse Events

All adverse events will be followed with appropriate medical management until resolved. Patients removed from study for unacceptable adverse events will be followed until resolution or stabilization of the adverse event. For selected adverse events for which administration of the investigational drug was stopped, a re-challenge of the subject with the investigational drug may be conducted if considered both safe and ethical by the Investigator.

7.4 Expedited Reporting

7.4.1 Reporting to the HDFCCC Data and Safety Monitoring Committee

If a death occurs during the treatment phase of the study or within 30 days after the last administration of the study drug(s) and it is determined to be related either to the study drug(s) or to a study procedure, the UCSF PI or his/her designee must notify the DSMC Chair (or qualified alternate) within 1 business day of knowledge of the event. The contact may be by phone or e-mail.

7.4.2 Reporting to Institutional Review Board

The Principal Investigator must report events meeting the UCSF CHR definition of “Unanticipated Problem” (UP) and the San Francisco VA Medical Center within 5 business days of his/her awareness of the event.

7.4.3 Expedited Reporting to the FDA

If the study is being conducted under an IND, the Sponsor (or the Sponsor-Investigator) is responsible for determining whether or not the suspected adverse reaction meets the criteria for expedited reporting in accordance with federal regulations (21 CFR §312.32).

The Sponsor (or Sponsor-Investigator) must report in an IND safety report any suspected adverse reaction that is both serious and unexpected. The Sponsor needs to ensure that the event meets all three definitions:

- Suspected adverse reaction (as defined in 7.1.4)
- Unexpected (as defined in 7.1.5)
- Serious (as defined in 7.1.6)

If the adverse event does not meet all three of the definitions, it should not be submitted as an expedited IND safety report.

The timeline for submitting an IND safety report to FDA is no later than **15 calendar days** after the Investigator determines that the suspected adverse reaction qualifies for reporting (21 CFR 312.32(c)(1)).

Any unexpected fatal or life-threatening suspected adverse reaction will be reported to FDA no later than **7 calendar days** after the Investigator’s initial receipt of the information (21 CFR 312.32(c)(2)).

Any relevant additional information that pertains to a previously submitted IND safety report will be submitted to FDA as a Follow-up IND Safety Report without delay, as soon as the information is available (21 CFR 312.32(d)(2)).

Please see Appendix 2 for further details on the UCSF Helen Diller Family Comprehensive Cancer Center (HDFCCC) Data and Safety Monitoring Committee (DSMC) policies and procedures.

8 Evaluation of Efficacy

8.1 Determination of Positive or Negative Disease Status

8.1.1 FET PET Blinded Reads

All imaging studies will be reviewed by three nuclear medicine physicians blinded to the patient's history and their pathology. Each physician will undergo a reader-training course that will involve FET PET cases not included in the study reads. Image interpretation will involve 1) qualitative, 2) quantitative, and 3) overall assessments.

1) Qualitative/Visual Assessment

For each lesion, readers will assess whether increased tracer uptake is consistent with progression/recurrence (positive) or TRC (negative).

2) Quantitative Assessment

Quantitative assessments will be performed on transaxial slices showing the highest FET accumulation, as described by Galldiks (6). The SUVmax, TBRmax and TBRmean and size information will be collected. Based on the quantitative assessments, readers will evaluate in a binary fashion for progression/recurrence (positive) or TRC (negative) as defined in Galldiks (6) (TBRmax ≥ 2.3 and/or TBRmean ≥ 2.0 for use in indeterminate cases).

3) Overall Assessment

Based on qualitative and quantitative assessments, readers will make an overall determination whether FET uptake is most consistent with progression/recurrence (positive) or TRC (negative). In cases where readers disagree with the quantitative assessment, based on their expert judgement, they will be prompted to provide comments. The overall assessment will be the positive or negative determination for FET PET.

8.1.2 Standard of Truth

8.1.2.1 Composite Standard of Truth

A composite standard of truth (CSOT) for recurrence or TRC will be evaluated by a panel of physicians (Truth Panel) independent of the FET images, FET imaging reports, or FET blinded reads. The CSOT will be determined based on histopathology reports and other available clinical information, including prior imaging, subsequent imaging, tumor board notes, clinical notes. Histopathology of the target lesion obtained (biopsy, resection) within three months after the PET imaging session will be reviewed (although the Truth Panel will have access for up to six months after the PET imaging session). There is no agreed upon cutoff for determining recurrent tumor in the setting of gliomas. A 20% cutoff is often used, but a truth panel will include a pathologist for manual re-review of histopathology. Positive for recurrence on follow-up imaging will be based on RANO 2.0 criteria (4).

For lesion-level reference standard, features of RANO will be leveraged as part of the overall assessment and will be considered in evaluating lesion-level results. Histopathology and imaging will be the primary factors used in the determination, followed by additional clinical data available as part of tumor board notes. From this data, an overall determination will be made for each individual lesion, and this will be considered together with the patient-level determination (as per RANO).

In patients where the histopathology and RANO determination are concordant, the patient will be characterized based on the concordant results. If the patient does not have subsequent imaging available (either the patient declined clinically or the lesion was resected and so not present on subsequent imaging), the patient will be characterized based on histopathology for lesions resected or as progressive disease if there is clinical decline or death.

There will be many complicating factors for the CSOT:

1. The use of steroids and bevacizumab can impact lesion enhancement independent of actual progression. For example, a lesion may have decreased enhancement after a patient starts bevacizumab, but in fact have progressive disease (pseudo- response). In this case the RANO determination would be PR, while the patient could be characterized as recurrent disease by the Truth Panel. In order to take this into consideration, the Truth Panel will look at subsequent imaging studies to determine the appropriate characterization.
2. The goal of this study is to characterize existing lesions on the FET PET. If new lesions develop on follow-up imaging that are not in the same location or related to the original lesion of concern at time of FET PET, this will not be characterized as recurrent disease. This same issue may exist with histopathology, where a new lesion geographically distinct from the baseline lesion may be sampled and positive for tumor, but the lesion of concern was unchanged and not biopsied. The Truth Panel will take this into account when determining the characterization of the lesion.
3. Patients without imaging or histopathology due to clinical progression (hospice and/or death) will be characterized as recurrent disease.

The CSOT of progression/recurrence (positive) or TRC (negative) will be determined for each individual lesion and for each subject overall.

8.1.2.2 Histopathology Standard of Truth

For cases with available histopathology, the histopathology standard of truth for recurrence (positive) or TRC (negative) will also be determined by the Truth Panel as an intermediate result while reviewing histopathology as part of their overall assessment of each lesion and each subject.

8.1.3 Comparison of FET PET to Standard of Truth

The results of the FET PET scan will be compared to a standard of truth (either CSOT or histopathology standard of truth, as described above).

8.1.3.1 Lesion-level Analyses

For lesion-specific analyses, lesions will be classified as either TP, FP, TN, or FN:

- True positive (TP): FET PET read as positive for progression/recurrence, standard of truth confirms tumor progression/recurrence.
- False positive (FP): FET PET read as positive for progression/recurrence, standard of truth does not confirm progression/recurrence.
- True negative (TN): FET PET read as negative for progression/recurrence, standard of truth confirms negative for progression/recurrence.

- False negative (FN): FET PET read as negative for progression/recurrence, standard of truth does not confirm progression/recurrence.
- For any lesion that is recorded by only one of the expected evaluations (either by a blinded reader or by the standard of truth) after receiving both evaluations, the non-recorded evaluation will be assessed as negative for determination of the lesion-specific result (TP, FP, TN, or FN).

8.1.3.2 Subject-level Analyses

Subject-level results will be determined for each reader based on the lesion-level result(s):

- First, each lesion will be determined as TP, TN, FP, or FN by comparing the FET PET determination to the standard of truth.
- If the subject has only one lesion, then the subject-level result (for that reader) will be the same as the lesion-level determination.
- If the subject has two or more lesions, then the subject-level result (for that reader) will be a lesion-level result according to the following hierarchy, based on the potential clinical impact of these reads.
 - TP > FP > FN > TN > Missing
 - For example, if a subject has one TP lesion and one FN lesion (according to a specific reader), then the subject-level result (according to that reader) will be TP.

8.2 Efficacy Analysis Variables

8.2.1 General Efficacy Analyses

Sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and misclassification rate will be presented per subject by individual reader. There will also be a majority rule summary of the three readers' results where the calculations are based on the FET PET result (positive or negative) agreed to by the majority of the readers (2 or 3 readers). Wilson's binomial (score) 95% confidence intervals will be presented for each reader and for majority rule result.

Standardized uptake value (SUV) and tumor-to-background ratio (TBR) will be summarized per lesion for each reader. Individual readers' results will be presented in a listing.

8.2.2 Efficacy Variables

The sensitivity and specificity of FET PET imaging will be calculated according to the above formula along with Wilson's binomial (score) 95% confidence intervals.

- **Sensitivity**

Sensitivity is defined as the proportion of study patients with a true positive (TP) FET PET scan relative to those with positive standard of truth result:

$$\text{Sensitivity (\%)} = [\text{TP} / (\text{TP} + \text{FN})] \times 100$$

- **Specificity**

Specificity is defined as the proportion of study patients with a true negative (TN) FET PET imaging result relative to those with a negative standard of truth result:

$$\text{Specificity (\%)} = [\text{TN} / (\text{TN} + \text{FP})] \times 100$$

The positive predictive value, the negative predictive value, accuracy, misclassification rate, standardized uptake value, and tumor-to-background ratio will be calculated as follows:

- **Positive predictive value (PPV)**

The positive predictive value is defined as the probability that a positive standard of truth result is obtained given that the result of the FET PET scan is positive.

$$\text{PPV (\%)} = [\text{TP} / (\text{TP} + \text{FP})] \times 100$$

- **Negative predictive value (NPV)**

The negative predictive value is defined as the probability that a negative standard of truth result is obtained given that the result of the FET PET scan is negative.

$$\text{NPV (\%)} = [\text{TN} / (\text{TN} + \text{FN})] \times 100$$

- **Accuracy**

The accuracy is defined as the probability that the FET PET scan result is correct.

$$\text{Accuracy (\%)} = [(\text{TP} + \text{TN}) / (\text{TP} + \text{FP} + \text{TN} + \text{FN})] \times 100$$

- **Misclassification Rate**

The misclassification rate is defined as the probability that the FET PET scan result is not correct.

$$\text{Misclassification Rate (\%)} = [(\text{FP} + \text{FN}) / (\text{TP} + \text{FP} + \text{TN} + \text{FN})] \times 100$$

- **Standardized Uptake Value (SUV) and Tumor-to-Background Ratio (TBR)**

Quantitative assessments will be performed on transaxial slices showing the highest FET accumulation. Quantitative analysis will be performed on the 20-40 minute imaging time point.

First, readers will determine the SUVmean of background normal tissue by marking a large region of interest (ROI) on the contralateral hemisphere in an area of unaffected brain tissue.

Second, a volume of interest will be placed around the lesion, and within that volume a threshold segmentation will be performed using a lower limit threshold of background SUVmean x 1.6.

Third, a 1.6 cm diameter circular ROI will be centered on the qualitatively hottest portion of FET uptake. TBRmax will be calculated by dividing the SUVmean of the 1.6 cm diameter circular ROI by the SUVmean of background normal tissue. TBRmean will be calculated by dividing the SUVmean of the lesion volume of interest (using the background SUVmean x 1.6 threshold) by the SUVmean of background normal tissue. Lesions will be quantitatively evaluated in a binary fashion as recurrence if TBRmax >

2.3 or treatment-related changes if TBRmax < 2.3. For indeterminate lesions, readers can use TBRmean to evaluate for recurrence vs. treatment-related changes.

Additionally, the SUVmax of the lesion and the SUVpeak will also be calculated.

9 Statistical Considerations and Evaluation of Results

9.1 Determination of Sample Size and Power Estimate

In protocol version 2.1 the primary analysis was amended to determine if FET PET can differentiate between benign treatment-related changes (TRC) and recurrent glioma in comparison to a composite standard of truth (CSOT) that includes pathology and other clinical information, evaluated using estimates of sensitivity and specificity. With the amendment of the primary endpoints, the study sample size calculations were updated.

1. [Section 9.1.1](#) describes the sample size calculation for analysis of the co-primary endpoints of sensitivity and specificity under protocol version 2.1.
2. [Section 9.1.2](#) describes the sample size calculation based on the initial planned analysis of misclassification rate, prior to protocol version 2.1.

9.1.1 Amended Sample Size Calculation - Protocol Version 2.1

For protocol version 2.1, the sample size was determined based on separate estimates of sample size for each of the co-primary endpoints (sensitivity and specificity). The greater of the two estimates was taken as the required sample size of the study. For each endpoint, the calculation computed the probability of whether the lower limit of a 95% Wilson confidence interval for a binomial proportion was greater than the null proportions of 0.70 and 0.68 for sensitivity and specificity, respectively. Other assumptions include prevalence of glioma recurrence=0.50, observed sensitivity=0.81, and observed specificity=0.79. The sample size for each estimate was set as the smallest positive integer that provides power ≥ 0.80 . Given these assumptions, the estimated sample size is N=118.

9.1.2 Initial Sample Size Calculation

Prior to protocol version 2.1, the initial study sample size was calculated for both populations. We expected that 60% of our patients would be imaged for recurrent disease after surgery and/or radiation therapy, and we expected that 40% of our patients would be imaged prior to initial therapy for glial malignancy.

Population 1: Initially, the study's primary endpoint was misclassification rate as our statistical endpoint, defined as the percentage of patients that are classified incorrectly as either recurrent disease and treatment related changes (ie misclassification rate = $[FP+FN]/[FP+FN+TP+TN]$).

True positive (TP): FET PET read as positive for tumor, pathology/follow-up demonstrates tumor recurrence in at least one biopsy sample.

False positive (FP): FET PET read as positive for tumor, pathology/follow-up negative tumor recurrence in none of the biopsy samples.

True negative (TN): FET PET read as negative for tumor, pathology/follow-up negative tumor recurrence in none of the biopsy samples.

False negative (FN): FET PET read as negative for tumor, pathology/follow-up demonstrates tumor recurrence in at least one biopsy sample.

The sample size was calculated based on three subpopulations:

1. **Recurrent metastatic disease:** We estimated that there would be a prevalence of 65% for recurrent metastatic tumor at time of imaging. Papers that estimate misclassification rate have shown a misclassification rate of 24% (sensitivity of 86.7%, specificity of 68.2%, and a prevalence of 43%) for perfusion MRI (9), a misclassification rate of 46% (sensitivity of 59%, specificity of 41%, and a prevalence of 75%) for lesion quotient MRI. For FET PET, the literature has shown a misclassification rate ranging from 7 to 17%:
 - Misclassification rate of 17% with a sensitivity of 83%, specificity of 85% and prevalence of 84% (10).
 - Misclassification rate of 7% with a sensitivity of 95%, specificity of 91% and prevalence of 48% (11).

For our sample size analysis, we used a binomial test for proportions. Assuming a misclassification rate of 35% for conventional MRI and 10% for FET PET, 34 patients needed to be imaged with pathologic correlation to demonstrate the difference with a significance level of 0.01 with a power of 90%, and a one-sided test. Our null hypothesis was that there is no difference between MRI and FET PET misclassification rates (H_{null} : MRI_misclass = FET PET misclass = 35%). The alternative hypothesis was that the FET PET misclassification rate is lower (H_{alt} : FET PET misclass < MRI_misclass = 35%). We estimated that 55% of patients would have pathology as a correlate, and we would replace all patients who did not have pathology within four weeks of imaging to fill our primary endpoint. Therefore the total patient population in population 1 with metastatic lesions was 62 patients.

2. **Recurrent high-grade glioma (Grade 3 and 4):** Based on prior data from UCSF, we anticipated that 70% of patients would have recurrent tumor at the time of imaging (12). Using this same paper as an estimate of misclassification rate using MRI for the characterization of recurrent tumor, resulted in a sensitivity of 82%, specificity of 76%, prevalence of 70% and a misclassification rate of 19.8%. For FET PET, the first paper to publish the sensitivity and specificity of FET PET was Rachinger et al in 2005; they reported a sensitivity, specificity and misclassification rate of 100%, 93% and 2% respectively (45 patients with a prevalence of 69%) (13). A subsequent paper published in 31 patients, 26 of whom had recurrent tumor, had a sensitivity of 100% and a specificity of 84%, resulting in a misclassification rate of 2.6% (14). A third paper looked at the ability to characterize pseudoprogression after radiochemotherapy all of whom had an enhancing lesion on MRI, demonstrated a sensitivity, specificity and misclassification rate of 100%, 91% and 5% respectively (6). No meta-analysis exists for estimating the accuracy of FET PET, and therefore we have selected 5% as a reasonable goal misclassification rate. Our null hypothesis was that there is no difference between MRI and FET PET misclassification rates (19.8% for MRI and 5% for FET PET). For our sample size analysis, we used a binomial test for proportions. Therefore, 27 patients needed to be imaged with pathologic correlation to demonstrate the difference with a significance level of 0.05 with a power of 80%, and using a one-sided t-test. Our null hypothesis was that there is no difference between MRI and FET PET misclassification rates (H_{null} : MRI_misclass = FET PET misclass = 19.8%). The alternative hypothesis was that the FET PET misclassification rate is lower (H_{alt} : FET PET misclass < MRI_misclass = 19.8%). We estimated that 40% of patients would have pathology as a correlate, and we would replace all patients who did not have pathology within four weeks of imaging to fill our primary endpoint. Therefore the total patient population in population 1 with high grade gliomas was 68 patients.

- 3. Recurrent low-grade glioma (Grade 1 and 2):** We included this population as a secondary endpoint in order to gain information on the role of FET PET in the characterization of low-grade gliomas. We aimed to image 20 patients as part of this cohort to obtain preliminary information about the role of FET PET in this population.

Population 2: For population 2 we selected a misclassification rate for the characterization of tumor as either low or high grade. Most of the data on the literature for the effectiveness of conventional imaging (MRI) for the classification of disease is reported as sensitivity and specificities; the best meta-analysis available suggests that MR spectroscopy has a sensitivity of 75% and a specificity of 70% (15). In this meta-analysis of 25 studies, there were 427 low-grade and 802 high-grade tumors, resulting in a prevalence of 65% for high-grade tumors. Assuming a prevalence of 65%, this would imply a misclassification rate of 27% for conventional imaging. Using a recent FET PET article that demonstrated a sensitivity and specificity of 100% and 73% respectively for the characterization of low-grade and high-grade gliomas with a prevalence of 52%, we estimated a misclassification rate of roughly 13% for FET PET (16). Therefore, our target misclassification rate was 13%. Our null hypothesis was that there is no difference between MRI and FET PET misclassification rates (27% for MRI and 13% for FET PET). For our sample size analysis, we used a binomial test for proportions. Therefore, 49 patients needed to be imaged with pathologic correlation to demonstrate the difference with a significance level of 0.05 with a power of 80%, using a one-sided test. Our null hypothesis is that there is no difference between MRI and FET PET misclassification rates (H_{null} : $\text{MRI_misclass} = \text{FET PET misclass} = 27\%$). The alternative hypothesis is that the FET PET misclassification rate is lower (H_{alt} : $\text{FET PET misclass} < \text{MRI_misclass} = 27\%$).

We estimated that 50 patients with intracranial neoplasms would be enrolled each year, and we estimated that we would enroll 199 patients over the four years of the study.

9.2 Analyses Plans

9.2.1 Analysis Populations

There will be two analysis populations. The first population will be patients with intracranial neoplasm (both glial and metastatic disease) previously treated with surgery and/or radiation therapy where there is concern for recurrent disease. The second population will be patients with suspicion or known glial malignancy planning on undergoing biopsy or surgery.

The safety analysis dataset will include all patients who completed initial FET PET imaging per protocol.

The efficacy analysis dataset will include all glioma patients who completed initial FET PET imaging per protocol (repeat FET PET imaging is excluded). FET PET scans that are not readable due to data or scanner errors will be excluded from efficacy analyses.

9.2.2 Analysis of Primary Endpoints

Sensitivity, specificity, and 95% confidence interval (CI) will be calculated per the formulas in [Section 8.2.2](#), using the definitions of TP, FP, TN, and FN from [Section 8.1.3](#) and the CSOT. This will be done on a subject-specific basis based on the blinded readers' overall assessment.

The lower boundary of the 95% confidence interval for sensitivity will be compared to the threshold of 0.70 and for specificity it will be compared to 0.68.

Overall study success criteria: the lower bounds of the 95% CIs of the primary analysis of sensitivity and specificity must be greater than or equal to 0.70 and 0.68 respectively for at least the same 2 out of 3.

9.2.3 Analysis of Secondary Endpoints

For the secondary endpoints for performance characteristics, both the composite reference standard and histopathology alone will be used in separate calculations. Only the efficacy analysis set will be analyzed for secondary efficacy endpoints; the per protocol population will not be analyzed. TP, FP, FN, and TN are defined as described in [Section 8.1.3](#).

Calculations will be done to determine the subject-specific and lesion-specific sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and misclassification rate for FET PET. These analyses will use the blinded readers' overall assessment, not the visual/qualitative or quantitative assessments.

For the secondary analyses of sensitivity, specificity, PPV, NPV, accuracy, and misclassification rate that use histopathology as the standard of truth, analysis will be performed only on subjects who have known histopathology status. No imputation will be made for these endpoints.

Inter-reader variability will be analyzed using Fleiss' kappa statistic to determine the agreement between three independent blinded readers in assessing FET PET images as recurrence or TRC. Separate analyses of inter-reader variability will be done for the readers' qualitative/visual assessments, quantitative assessments, and overall assessments.

Intra-reader variability will be analyzed based on a random sample of 15 subjects whose images were re-reviewed by the same reader. The percent of agreement between the two interpretations will be computed for each reader. Cohen's kappa statistics will be used to determine the reproducibility of the assessment by individual readers when analyzing the same data repeatedly. Separate analyses of intra-reader variability will be done for the reader's qualitative/visual assessments, quantitative assessments, and overall assessments.

9.2.4 Exploratory Analysis

Exploratory analysis will be performed on patients with glioma who are under suspicion for progression or recurrence. For these participants, standard-of-care MRI performed during the FET PET/MRI will undergo retrospective analysis by a panel of three blinded independent neuroradiologists. The neuroradiologists will classify the findings as positive (indicating recurrence) or negative (indicating TRC) and compare them with the CSOT. The 3 readers will be blind to 18F-FET PET images, prior imaging results, clinical data, surgical reports, and histopathological results.

SUV and TBR results (SUVmean, SUVmax, SUVpeak, TBRmean, and TBRmax) will be summarized by descriptive statistics for each reader on a lesion-specific basis.

Exploratory analysis will also be performed to assess relationships between serial FET PET and clinical outcome (benign TRC and recurrence) in patients with recurrent metastatic lesion, recurrent high-grade gliomas and recurrent low-grade gliomas (Population 1).

Exploratory analyses will also be performed to determine if FET PET can differentiate between benign TRC and recurrent metastatic lesions and to determine if FET PET can accurately differentiate between low-grade and high-grade gliomas in population 2.

10 Study Management

10.1 Pre-study Documentation

This study will be conducted in accordance with the ethical principles that have their origin in the Declaration of Helsinki as stated in 21 CFR §312.120(c)(4); consistent with GCP and all applicable regulatory requirements.

Before initiating this trial, the PI will have written and dated approval from the Institutional Review Board for the protocol, written informed consent form, subject recruitment materials, and any other written information to be provided to participants before any protocol related procedures are performed on any participants.

The PI must comply with the applicable regulations in Title 21 of the Code of Federal Regulations (21 CFR §50, §54, and §312), GCP/ICH guidelines, and all applicable regulatory requirements. The IRB must comply with the regulations in 21 CFR §56 and applicable regulatory requirements.

The clinical investigation will not begin until either FDA has determined that the study under the Investigational Drug Application (IND) is allowed to proceed or the FDA has determined that the study is exempt from IND requirements.

10.2 Institutional Review Board Approval

The protocol, the proposed informed consent form, and all forms of participant information related to the study (e.g. advertisements used to recruit participants) will be reviewed and approved by the UCSF CHR (UCSF Institutional Review Board). Prior to obtaining CHR approval, the protocol must be approved by the Helen Diller Family Comprehensive Cancer Center Site Committee and by the Protocol Review Committee (PRC). The initial protocol and all protocol amendments must be approved by the IRB prior to implementation.

10.3 Informed Consent

All participants must be provided a consent form describing the study with sufficient information for each participant to make an informed decision regarding their participation. Participants must sign the IRB -approved informed consent form prior to participation in any study specific procedure. The participant must receive a copy of the signed and dated consent document. The original signed copy of the consent document must be retained in the medical record or research file.

10.4 Changes in the Protocol

Once the protocol has been approved by the UCSF CHR, any changes to the protocol must be documented in the form of an amendment. The amendment must be signed by the Investigator and approved by PRC and the CHR prior to implementation.

If it becomes necessary to alter the protocol to eliminate an immediate hazard to patients, an amendment may be implemented prior to CHR approval. In this circumstance, however, the Investigator must then notify the CHR in writing within five (5) working days after implementation. The Study Chair and the UCSF study team will be responsible for updating any participating sites.

11 Protection of Human Subjects

11.1 Protection of Privacy

Participants will be informed of the extent to which their confidential health information generated from this study may be used for research purposes. Following this discussion, they will be asked to sign the HIPAA form and informed consent documents. The original signed document will become part of the participant's medical records, and each participant will receive a copy of the signed document. The use and disclosure of protected health information will be limited to the individuals described in the informed consent document.

Appendix 1 Schedule of Study Procedures and Assessments

| Schedule of Study Procedures and Assessments | | | | |
|---|------------------------------------|--------------------|---|-----------------------------------|
| Period/ Procedure | Screening (Day -30 to Day 1) | Imaging (Day 1) | Follow-up (Off-Study, Until biopsy, resection, or imaging) | Imaging ¹ (Day 30+) |
| Informed consent | X | | | |
| Pregnancy test (women of childbearing potential only) | | X | | X |
| Vital signs | | X ² | | |
| Imaging Procedure | | | | |
| FET administration | | X | | X |
| Sedation/anesthesia* | | X | | X |
| PET imaging | | X | | X |
| Adverse event reporting | | X ³ | | X ³ |
| Follow-up | | | | |
| Correlation with pathology, imaging | | | X | |

*sedation and anesthesia will be administered only in patients where it is required

¹ Optional study procedure

² Evaluation of vital signs 20 min prior to administration of radiotracer (± 60 min) and 20 min after completion of imaging (± 60 min)

³ Evaluation of adverse events 20 min after completion of imaging (± 60 min)

Appendix 2 Data and Safety Monitoring Plan a Non-therapeutic Institutional Trial

1. Oversight and Monitoring Plan

The UCSF Helen Diller Family Comprehensive Cancer Center (HDFCCC) Data and Safety Monitoring Committee (DSMC) is responsible for monitoring data quality and participant safety for all HDFCCC institutional clinical trials. A summary of DSMC activities for this trial includes:

- Annual auditing
- Review of serious adverse events
- Minimum of biennial regulatory auditing

2. Monitoring and Reporting Guidelines

Investigators will conduct a continuous review of data and participant safety at monthly site committee meetings where the status of each participant is discussed and documented in the site committee minutes.

For “greater than minimal risk” nontherapeutic trials, the assigned DSMC Senior Monitor/Auditor will audit three of the enrolled participants once per year, with a maximum of ten participant charts audited during the entire course of auditing this trial until IRB closure.

If blood or tissue banking trials are determined to be “greater than minimal risk”, then only Serious Adverse Events (SAEs) recorded in OnCore will be reviewed at each DSMC meeting for these trials.

After completion of each auditing visit, the DSMC Monitor/Auditors will send a follow-up report to the study team within 20 business days after the auditing visit is complete for the PI and the study team to resolve all action items from this report within 20 business days. An abbreviated regulatory review (i.e., reviewing protocol and consent versions, SAEs, PVs, DOA logs, 1572 forms, etc.) will occur at each participant monitoring review; however, a full regulatory review will occur on a biennially basis by the DSMC for regulatory compliance.

Auditing of all enrolled participants in these trials will be complete after 10 enrolled participants have been audited. However, regulatory reviews of the trial, safety reviews (i.e., Serious Adverse Event (SAE) reviews and Protocol Violation (PV) reviews), and audit/inspection preparation (as applicable) will continue until the trial is closed by the IRB.

3. Review and Oversight Requirements

3.1 Adverse Event Monitoring

All Grade 3-5 adverse events (AEs), whether or not considered expected or unexpected and whether or not considered associated with the study intervention or procedure, will be entered into OnCore®, UCSF’s Clinical Trial Management System.

Adverse events are graded according to the Common Terminology Criteria for Adverse Events (CTCAE) as developed and revised by the Common Therapy Evaluation Program (CTEP) of the National Cancer Institute. Adverse events are further given an assignment of attribution or relationship to study intervention or procedure. Attribution categories are:

- **Definite** – clearly related to the study intervention or procedure.
- **Probable** – likely related to study intervention or procedure.
- **Possible** – may be related to study intervention or procedure.
- **Unrelated** – clearly not related to the study intervention or procedure.

All clinically significant adverse events entered into OnCore® will be reviewed on a monthly basis at the Site Committee meetings

3.2 Serious Adverse Event Reporting

By definition, an adverse event is defined as a serious adverse event (SAE) according to the following criteria:

- Death
- Life-threatening adverse experience*,
- Inpatient hospitalization or prolongation of existing hospitalization,
- Persistent or significant disability/incapacity,
- Congenital anomaly/birth defect, or cancer, or
- Any other experience that suggests a significant hazard, contraindication, side effect or precaution that may require medical or surgical intervention to prevent one of the outcomes listed above,
- Event that changes the risk/benefit ratio of the study

* A life-threatening adverse experience is any AE that places the patient or subject, in the view of the investigator, at immediate risk of death from the reaction as it occurred, i.e., it does not include a reaction that, had it occurred in a more severe form, might have caused death.

Serious adverse event reporting will be in accordance with all IRB regulations. For trials conducted under an investigational new drug (IND) application, the SAE will be reported in accordance with Code of Federal Regulation Title 21 Part 312.32 and will be reported on a Med Watch form.

UCSF IRB website for guidance in reporting serious adverse events:

<https://irb.ucsf.edu/adverse-event>

Med Watch forms and information:

www.fda.gov/medwatch/getforms.htm

All serious adverse events are entered into OnCore, as well as submitted to the IRB. The SAEs are reviewed and monitored by the Data and Safety Monitoring Committee on an ongoing basis and discussed at DSMC meetings, which take place every six weeks. The date the SAE was sent to all required reporting agencies will be documented in OnCore.

If a death occurs during the treatment phase of the study and is determined to be possibly, probably, or definitely related either to the study intervention or procedure, the Investigator or his/her designee must notify the DSMC Chair or Vice Chair and DSMC Director within one business day.

3.3 Review of Adverse Event Rates

If at any time the Investigator voluntarily holds enrollment or stops the study due to safety issues, the DSMC Chair (or Vice Chair) and the DSMC Director must be notified within one business day and the IRB must be notified as per IRB reporting requirements.
