Emulation of the PALOMA-2 trial using specialty oncology electronic health records databases

NCT06659744

18th August 2025

1. Title Page

Title	Emulation of the PALOMA-2 (NCT01740427) trial using specialty oncology electronic health records databases
Research question & Objectives	Emulation of the PALOMA2 (NCT01740427) trial, which compared palbociclib–letrozole to letrozole alone on progression-free survival (PFS) as primary and overall survival (OS) as secondary analysis in postmenopausal women with estrogen receptor (ER)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer
Protocol version	V1.1

Table of contents

2. Abstract

This trial emulation study aims to emulate the PALOMA-2 trial (NCT01740427) using real-world specialty oncology electronic health records data and to investigate the concordance between the trial's original and the emulated treatment effect estimate on overall survival (OS). PALOMA-2 was a Phase III, randomized, double-blind study evaluating the efficacy and safety of palbociclib (125 mg orally, once daily for 21 days followed by 7 days off) in combination with letrozole (2.5 mg orally, once daily, continuously) versus placebo plus letrozole in postmenopausal women with estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2−) advanced breast cancer who had not received prior systemic treatment for their advanced disease.

3. Amendments and updates

Version date	Version number	Section of protocol	Amendment or update	Reason

August 18 , 2025	V1.1	4. Rationale and background 5. Research question and objective 6. Research methods	Refinement of text based on FDA feedback	NA

4. Rationale and background

Randomized controlled trials (RCTs) are generally regarded as the gold-standard of evidence for establishing efficacy of medical products. However, real-world data (RWD) are increasingly used to complement evidence from RCTs. Yet, to have confidence in the accuracy in the accuracy of treatment efficacy estimates from RWD, investigators need to know what questions can be validly answered, with which non-interventional study designs, and which analysis methods are appropriate, given the data that is available. Building on a process from the RCT DUPLICATE initiative.[1-4] **EmulatioN of Comparative Oncology trials with Real-world Evidence (ENCORE)** is the trial emulation discussed in this protocol is part of the expansion project specific to oncology and aims to emulate 12 randomized oncology RCTs using multiple EHR data sources.

The purpose of this protocol is to describe the emulation of the **PALOMA-2** trial. PALOMA-2 was a Phase III, double-blind, randomized study assessing the efficacy and safety of **palbociclib (125 mg orally, once daily for 21 days of a 28-day cycle) in combination with letrozole (2.5 mg orally, once daily, continuously)** versus **letrozole alone** in postmenopausal women with **estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2−) advanced breast cancer** who had not received prior systemic treatment for their advanced disease.

3

The primary trial endpoint was **progression-free survival (PFS)** with a hazard ratio (HR) of **0.58** (95% CI, 0.46 to 0.72), based on a **median PFS of 24.8 months** (95% CI, 22.1 to not estimable) in the palbociclib-plus-letrozole group compared with **14.5 months** (95% CI, 12.9 to 17.1) in the letrozole-alone group. The FDA granted palbociclib accelerated approval in [February 2015](#), in combination with letrozole for the treatment of ER-positive, HER2-negative advanced breast cancer as initial endocrine based therapy in postmenopausal women.

Overall survival (OS) was a secondary trial endpoint with a hazard ratio of **0.96** (95% CI, 0.78 to 1.18; one-sided p = 0.34) based on a median OS of 53.9 months in the palbociclib-plus-letrozole group and 51.2 months in the letrozole-alone group.

The results of the PFS endpoint were published in the *NEJM* on November 17, 2016 ([PMID 27959613](#)).[5]

The results of the OS endpoint were published in the *J. Clin. Oncol.* on January 22, 2024 ([PMID 38252901](#)).[6]

5. Research question and objectives

The primary and secondary research question is summarized in Table 1.

A. Primary research question and objective

Table 1. Primary and secondary research questions and objective.

Objective:	To compare the overall survival [OS] in patients who initiated palbociclib plus letrozole versus patients who initiated letrozole alone.
Hypothesis:	Initiation of palbociclib plus letrozole improves OS time as compared to initiation of letrozole alone.
Population *(mention key inclusion-exclusion criteria):*	- Age ≥18 years - Postmenopausal women with ER-positive, HER2-negative locally advanced or metastatic breast cancer who receive treatment without curative intent - The line of therapy for patients in EDB1 and EDB3 is implicitly advanced/metastatic because the line of therapy classification starts after their advanced/metastatic diagnosis in the respective database - In EDB4, patients must explicitly have any evidence of a metastasis prior initiating palbociclib plus letrozole or letrozole alone - Adenocarcinoma histology

	• No prior systemic treatment for advanced/metastatic disease • ECOG 0 or 1
Exposure:	Initiation of palbociclib plus letrozole
Comparator:	Initiation of letrozole
Outcome:	Primary: Time to all-cause mortality (OS) Secondary: Time to next treatment (TTNT)
Time *(when follow up begins and ends):*	From the day of treatment initiation until outcome. Death, last observed clinical activity/last sign of the patient being alive, or data cut-off, whichever occurred earliest
Setting:	1L ER-positive, HER2-negative locally advanced or metastatic adenocarcinoma of the breast
Main measure of effect:	Hazard ratio (95% CI) for OS

The emulation of the main protocol elements of the PALOMA-2 is illustrated side by side in **Table 2**.

Table 2. Trial emulation table summarizing the main protocol elements of the PALOMA-2 trial and the planned emulation.

Protocol component	PALOMA-2 RCT	Emulation	Comments
Eligibility criteria	• Women aged ≥18 years with diagnosis of breast cancer	• Female aged ≥18 years at treatment initiation with a diagnosis of breast cancer	
	• Histologically or cytologically confirmed adenocarcinoma of the breast	• Diagnosis of breast adenocarcinoma via histology/pathology records	
	• Locoregionally recurrent or metastatic disease not amenable to curative resection/radiotherapy	• Evidence of metastatic or recurrent disease	
	• ER-positive status	• Documentation of ER-positive (or -missing) status	• If ER is missing and a patient received the exposures of interest, then ER is likely to be positive given the alignment with the indication for the exposures of interest

	• HER2-negative status	• Documentation of HER2-negative (or -missing) status	• If HER2 is missing and a patient received the exposures of interest, then HER2 is likely to be negative given the alignment with the indication for the exposures of interest
	• Postmenopausal status	• N/A	• Although not directly captured in RWD, it is likely to be fulfilled given the alignment with the indication for the exposures of interest
	• No prior systemic therapy for advanced/metastatic ER+ disease	• No systemic anti-cancer therapy* following initial record indicating metastatic disease and prior to index date	
	• Measurable disease per RECIST v1.1 or bone-only disease confirmed by imaging	• N/A	• It is reasonable to assume that all patients in RWD had evidence of disease if they received treatment; additionally OS primary endpoint does not require measurable disease
	• WHO/ECOG performance status 0 or 1	• WHO/ECOG performance status of 0 or 1 within 90 days of index date	
	• No symptomatic, life-threatening visceral disease (e.g., massive effusions, >50% liver involvement)	• N/A	• This is a safety criterion for the trial and less relevant to real-world treatment setting, given that patients received treatments of interest
	• No active or symptomatic CNS metastases	• Record of CNS metastases prior to or on index date	
	• No prior treatment with CDK4/6 inhibitors	• Exclude patients with prior CDK4/6 inhibitor exposure	
	• No recurrence during or within 12 months of adjuvant non-steroidal AI (anastrozole or letrozole)	• Treatment with letrozole or anastrozole ≤12 Months prior to date of metastatic diagnosis	
	• No other malignancy within 3 years	• No prior record of non-breast malignancy within 3 years	
Treatment strategies	Palbociclib + letrozole vs. placebo + letrozole	Patients initiating palbociclib + letrozole vs. letrozole alone	Use treatment start dates to define exposure
Assignment procedures	Randomized 2:1 to palbociclib + letrozole or placebo + letrozole	Propensity score–based matching or weighting to emulate randomization	Balance baseline covariates to reduce confounding
Follow-up period	Time from randomization to death or censoring	Time from treatment initiation to death or censoring	
Outcome	Primary: Progression-free survival (PFS) per investigator assessment Secondary: Overall survival (OS)	Primary: OS Secondary: Time-To-Next-Treatment (TTNT)	Lack of good measurement of progression, so inferred by initiation of next treatment as a secondary endpoint rather than primary

| Causal contrast | Intent-to-treat effect | Effect of initiating palbociclib + letrozole versus letrozole | Analogous to ITT; emulates initiation rather than adherence |

*Includes the following: alpelisib, capecitabine, carboplatin, cisplatin, cyclophosphamide, docetaxel, doxorubicin, epirubicin, eribulin, exemestane, fluorouracil, gemcitabine, goserelin, ixabepilone, methotrexate, olaparib, paclitaxel, tamoxifen, talazoparib, toremifene, and vinorelbine.

6. Research methods

6.1. Data sources

6.1.1. Context and rationale for data sources

The overall ENCORE project uses data from a total four different oncology-specific electronic health records (EHR)-derived data sources: ConcertAI, COTA, Flatiron Health, McKesson/Ontada. For ENCORE, not all databases are available for each cancer indication and the names of the databases will henceforth be blinded and referred to as ENCORE DataBase (EDB) 1, 2, 3 and 4 (the numbering does not coincide with the above order of mention of the databases).

For this trial emulation, breast cancer-specific data are available for EDB1, EDB3 and EDB4. The fitness-for-purpose of the data for the given trial emulation were assessed and considered for the final selection of the databases.

Reason for selection: All considered databases draw from a comprehensive national sample of patients with cancer in the US with detailed EHR-derived information on the information necessary to study medication effectiveness in oncology.

Strengths of data source(s): Size and detailed clinical information on oncology-specific variables and outcomes (validated composite all-cause mortality sourced from different data sources[7,8]).

Limitations of data source(s): General limitations across all data sources include missing data, potential lack of data continuity, heterogeneous data provenance, quality/heterogeneous ascertainment of mortality endpoint data and the variability in how line of treatment is captured and curated (a more comprehensive discussion of the data sources and approaches is provided in section 7. After a comprehensive assessment of all data sources regarding their fitness for the purpose of emulating the PALOMA-2 trial. For these reasons, only EDB1 and EDB3 will be used for the main analysis. However, EDB4 will be considered as part of a sensitivity analysis in which all databases are individually analyzed and treatment effect estimates are pooled using a meta-analytic fixed effects model (see sensitivity analysis #11 in Table 8).

Data source provenance/curation: In brief, all databases provide EHR-derived oncology-specific patient-level information which are either derived directly (e.g., through structured data fields and dropdown menu selections) from EHR and/or undergo semi-automated abstraction processes from unstructured reports. The detailed data provenance, abstraction processes and implemented business rules to curate and prioritize certain variables may vary by database and can be found in legacy publications by the data partners.

Table 3. Metadata about data sources and software.

	EDB1	EDB3	EDB4
Data Source(s):	EHR-derived	EHR-derived	EHR-derived
Study Period:	Patient identification period: 01/01/2011-04/30/2024 with follow-up information through data cut-off date on 04/30/2024	Follow-up information through June 2023 (there is no specific time period restrictions for patient eligibility)	Patient identification period: 10/01/2018-09/30/2023 with follow-up information through data cut-off date on 09/30/2023.
Eligible Cohort Entry Period:	Anytime at start of study drug initiation	Anytime at start of study drug initiation	Anytime at start of study drug initiation
Data Version (or date of last update):	Delivery: Jul 11, 2024	Delivery: Jun 16, 2023	Delivery: Oct 24, 2023 Updated (demographics): Feb 29, 2024
Data sampling/extraction criteria:	Patients are sampled if they have a confirmed diagnosis of metastatic breast cancer via abstraction on or after 1 Jan 2011, and at least 2 EHR visits on or after 1 Jan 2011. Both ICD-9 (174.x) and ICD-10 (C50.x) codes are used for the initial selection, and advanced diagnosis are then confirmed via abstraction (since ICD codes do not specify advanced diseases).	This database identifies patients for curation using a structured ICD-10 diagnosis code (ICD-10 C50*), corresponding to the indication of interest, along with at least the year of diagnosis. Once this initial screening list is generated, patients are randomly selected for further review. Curation begins with confirmation of the diagnosis and diagnosis date, primarily based on pathology reports and other unstructured data sources. All patients must be over 18 years of age at the time of their first diagnosis. Certain breast cancer cases are excluded from curation. Specifically, in-situ breast cancers such as ductal carcinoma in situ (DCIS) or lobular carcinoma in situ (LCIS) without an invasive component are not eligible. However, DCIS with microinvasion or DCIS associated with Paget's disease qualifies for curation. Additionally, in-situ breast cancers that later progress to invasive carcinoma are eligible; in	Breast cancer patients with an office visit in the reporting period will be included in the report with full patient history. Patients are sampled if they were diagnosed with breast cancer and with a documented visit date, within the defined reporting period, to one of the network facilities and were at least 20 years of age at the time of first diagnosis. Patients who were on a clinical trial at any point in their treatment history are excluded.

	these cases, the diagnosis date should reflect the date of the original in-situ diagnosis, not the later invasive diagnosis. Patients are ultimately selected for inclusion in data products through quality control processes that assess consistency and potential conflicts in their records. These evaluations may rely on structured data alone or a combination of structured and curated data, depending on the specific data product. Importantly, CAI does not exclude patients based on data completeness, in order to prevent the introduction of selection bias.	
Type(s) of data:	EHR-derived	EHR-derived	EHR-derived
Data linkage[1]:	Mortality/date of death is a composite endpoint of structured and unstructured data from the EHR, obituary data, and the social security death index	Mortality/date of death is a composite endpoint derived from structured EHR data, manual curation, and third-party sources including obituary data and the Social Security Death Index. De-identified tokens link patients across datasets using hashed PII. Curated data is prioritized, followed by EHR and then third-party sources. Reported death dates are shifted to the nearest Sunday within four days to enhance privacy. Curated death information follows a source hierarchy: death certificate, obituary, or provider-reported date.	Mortality/date of death is a composite endpoint of structured EHR data and linked commercial data from clearinghouse providers hosted by Datavant.
Conversion to CDM[2]:	No	Yes	No
Software for data management:	R 4.3.2	R 4.3.2	R 4.3.2

[1] Mortality/date of death is a composite endpoint that is often derived from various linked sources including social security death index/ Social Security Administration death master file, obituary data and EHR records
[2] CDM = Common Data Model

6.2. Data management

Data is stored on secure Mass General Brigham corporate provisioned and backed up servers physically located in our Mass General Brigham corporate data centers. Mass General Brigham corporate data centers are designed to insure availability of the affiliated hospitals' and research applications and IT systems in the event of a disaster. The Division follows Mass General Brigham workstation requirements which include: encryption at rest, up-to-date malware protection including antivirus, spyware detection and removal tools, Crowdstrike End Point protection installed, devices enrolled in enterprise Mobile Device Management (MDM) solution as appropriate, any laptop/computer used for business purposes must not be shared with family, friends, or other unauthorized individuals, and compliance with enterprise Password Requirements. Only authorized personnel have read-only access to raw data files.

Cleaned and analysis-ready datasets, i.e., +/- imputed one-row-per-patient tables with all required exposure, outcome and covariate variables, are stored in separate sub-directories dedicated for the specific emulated trial.

6.3. Quality control

Upon delivery, data quality procedures included checks on delivered tables and variables, per table checks, descriptives on most important measures such as demographic and stage distributions by sex at time of initial diagnosis, regimen/exposure frequency counts and time-trends and overall survival benchmarks against literature and general cancer registry statistics. The R code to reproduce the quality assessments is deposited on the Mass General Brigham-provisioned GitLab server https://gitlab.partners.org/drugepi/encore/quality (repository is only accessible within the Mass General Brigham network and additionally only to authorized study personnel).

6.4. Study design

<u>Research design (e.g. cohort, case-control, etc.)</u>: Cohort study

<u>Rationale for study design choice</u>: Resembles the principles of the (target) trial emulation framework.[9]

6.5. Study design diagram

Figure 1 depicts study design and variable measurement considerations for the emulation of the PALOMA-2 trial. The selection of key confounders/prognostic factors is driven by expert knowledge and additionally based on covariates included in the real-world prognostic score (ROPRO) which is a published and validated pan-tumor and cancer-specific prognostic score framework for overall survival.[10-14]

Figure 1. Study design illustration for PALOMA-2 trial emulation.

Cohort Entry Date
(Initiation of palbociclib plus letrozole versus letrozole alone)
Day 0

First metastatic breast cancer
Day MBC

Inclusion Assessment Window
Days [0, 0]
(age ≥ 18)

Inclusion
[-inf, 0]
- Metastatic breast cancer
- Estrogen receptor positive (ER+)

Inclusion Assessment Window
Days [MBC, -1]
Untreated with systemic anticancer therapy for metastatic ER+ disease

Inclusion Assessment Window
Days [-90, 0]
ECOG performance status of 0 or 1

Exclusion
[-inf, 0]
- HER2+
- CNS metastases

Exclusion
[-inf, -1]
- Prior treatment with CDK4/6 inhibitor

Exclusion Assessment Window
Days [-1095, 0]
Non-breast cancer malignancy other than basal/squamous cell skin cancer or carcinoma in situ of cervix

Exclusion Assessment Window
Days [-365, MBC-1]
Treatment with non-steroidal aromatase inhibitor (ie anastrozole, letrozole)

Exclusion Assessment Window
Days [0, 0]
Systemic anticancer therapy other than palbociclib or letrozole

Covariate Assessment Window
Days [0, 0]
Age, sex, race/ethnicity, index year, region

Covariate Assessment Window

Covariate Assessment Window
Days [-90, 0]b

Follow up Window
Days [+1, Censorc]

a. De novo metastatic status, time initial diagnosis to T0, time from first evidence of metastatic disease to T0, # metastatic sites, smoking, family history, race/ethnicity, etc.
b. Labs (albumin, hemoglobin, etc.) and vitals (BMI, etc.) that are part of the ROPRO prognostic score; see Becker, Weberpals, et al. Ann Oncol 2020 (doi: 10.1016/j.annonc.2020.07.013)
c. Intention-to-treat: death due to any reason or last observed clinical activity/sign of patient being alive or data cut-off date (whichever occurred earlier)
No observability criterion was applied because measures like continuous enrollment periods (claims data) are not available in electronic health records.

6.6. Setting

6.6.1. Context and rationale for definition of time 0 (and other primary time anchors) for entry to the study population

Time 0 in this database study is defined as the date a patient initiated palbociclib plus letrozole (exposure) or letrozole alone (comparator) as part of their 1L systemic antineoplastic treatment for advanced/metastatic adenocarcinoma of the breast. This aims to emulate the date of randomization and cohort entry in the RCT (the time from randomization to first dose is not reported in the [clinicaltrials.gov study report](clinicaltrials.gov) or the trial articles).

6.6.2. Context and rationale for study inclusion criteria

Study inclusion criteria were defined to emulate all key inclusion criteria for the trial that were deemed both clinically relevant and measurable in EHR data. See Excel appendix table 1 (Table1_I_E) for a one-by-one evaluation. A summary of the operational definitions of the inclusion criteria that were applied for each database can be found in the Excel appendix Table 2. A flowchart of the study cohort assembly is provided in Appendix 3.

6.6.3. Context and rationale for study exclusion criteria

Study exclusion criteria were defined to emulate all key exclusion criteria for the trial that were deemed both clinically relevant and measurable in EHR data. See Excel appendix table 1 (Table1_I_E) for a one-by-one evaluation. A summary of the operational definitions of the exclusion criteria that were applied for each database can be found in the Excel appendix Table 2. A flowchart of the study cohort assembly is provided in Appendix 3.

6.6.4. Context and rationale for exposure(s) of interest

The exposure and comparator were defined to emulate the agents compared for the trial, i.e., initiation of palbociclib plus letrozole versus letrozole alone in a 1L metastatic setting.

- **EDB1**: Exposure is derived using a manually curated line of therapy (LOT) table provided by the data partner that programmatically categorizes treatment regimens into a coherent line of treatment. That is, each patient is represented with one row per curated line of therapy with corresponding information on line number, regimens as well start and end dates. Based on this table, patients are identified who received palbociclib-plus-letrozole or letrozole-alone treatment regimen by their generic names (string match) in 1L. The LOT implicitly only considers regimens that were given as part of a metastatic disease setting. More details and annotated code to identify initiators can be found in the 'Derive cohort EDB1' Quarto report (access within MGB network only).

- **EDB3**: Exposure is derived using a manually curated line of therapy (LOT) table provided by the data partner that programmatically categorizes treatment regimens into a coherent line of treatment. That is, each patient is represented with one row per curated line of therapy AND drug name with corresponding information online number, regimens as well start and end dates. Based on this table, patients are identified who received only palbociclib and letrozole within the first line of therapy, and letrozole alone within the first line of therapy by their generic names (string match). The LOT implicitly only considers regimens that were given as part of a metastatic disease setting. More details and annotated code to identify initiators can be found in the 'Derive cohort EDB3' Quarto report' (access within MGB network only).

- **EDB4:** For the EDB4 database, the following logic is applied.

- Identify patients with evidence of a metastasis from the diagnosis table in which the earliest date associated with evidence of metastasis is captured as a structured field (metastasis date).

- Identify all potential antineoplastic drugs typically used in advanced/metastatic breast cancer (see list below*). Only these are considered.

- Identify patients who received any of the PALOMA-2 drugs as the first antineoplastic treatment on or after the metastasis date.

- Identify and exclude patients who received palbociclib before the metastasis date.

*Antineoplastic drugs considered: abemaciclib, alpelisib, anastrozole, atezolizumab, bevacizumab, capecitabine, carboplatin, cisplatin, cyclophosphamide, docetaxel, doxorubicin, entrectinib, epirubicin, eribulin mesylate, etoposide, everolimus, exemestane, fluorouracil (5-FU), fulvestrant, gemcitabine, goserelin, ixabepilone, larotrectinib, lapatinib, letrozole, margetuximab, methotrexate, mitomycin, mitoxantrone, nab-paclitaxel, neratinib, olaparib, paclitaxel, palbociclib, PARP inhibitor therapy, pembrolizumab, pertuzumab, ribociclib, sacituzumab govitecan, talazoparib, tamoxifen, toremifene, trastuzumab, trastuzumab deruxtecan, trastuzumab emtansine (T-DM1), tucatinib, vinblastine, vincristine, and vinorelbine.

6.6.5. Context and rationale for outcome(s) of interest

The primary outcome for the database study was defined to emulate the primary outcome for the trial, time from index to death due to any reason (OS). Operational definitions:

- **EDB1**: Time in [days, months and years] from index date to death due to any reason. The date of death is de-identified to month-level granularity or (rarely) to year-level granularity and the date of death is therefore imputed to the 15th of a month or mid-year/July 2 of the year of death, respectively. In If there is no indication that a patient died during the study period, the patient is censored. The censoring date is defined as the last visit or treatment encounter or data cut-off date, whichever occurred earlier. The OS endpoint is operationalized using a parameterized R function *edb1_get_os()* and more details can be found in the attached pdf documentation.

- **EDB3**: Time in [days, months and years] from index date to death due to any reason. The date of death is de-identified to month-level granularity and the day of death is therefore imputed to the 15th of a month. Patients without evidence of death are censored at the earlier of the last recorded activity date or the data cut-off date. Activity dates are defined as documented in Table 4. Death dates are compiled from Electronic Medical Records (EMR), manual curation, and third-party death data, linked via de-identified tokens generated from hashed personally identifiable information (PII). Sources of death dates are prioritized as follows: (1) manual curation, (2) EMR, and (3) third-party sources. For privacy reasons, the final reported death date is shifted to the nearest Sunday within four days of the actual date. Manually curated death dates follow a prioritization hierarchy of source documentation: death certificate first, followed by scanned obituaries or death announcements, and lastly exact dates reported by providers without other supporting documentation. The OS endpoint calculation uses a parameterized R function (*edb3_get_os()*), with detailed documentation provided in the attached PDF.

- **EDB4**: Time in [days, months and years] from index date to death due to any reason. The date of death is de-identified to month-level granularity and the day of death is therefore imputed to the 15th of a month. If there is no indication that a patient died during the study period, the patient is censored. The censoring date is defined as the last date of vital signs recorded as proof that the patient was alive at that time (de-identified to week-level granularity) or

data cut-off date, whichever occurred earlier. The OS endpoint is operationalized using a parameterized R function *edb4_get_os()* and more details can be found in the attached pdf documentation.

Table 4. Relevant clinical activities considered to derive last activity date for censoring.

Table / clinical activity considered	Dates considered
Adverse events	Event date
Therapy (cellular, systemic, radiation, surgery)	Start and end dates or declined intervention date, surgery date, assessed resection dates
Palliative care referral	Referral date
Visits	Contact/visit date
Vitals	Assessed date
Labs	Lab date
Biomarkers	Specimen collection date
Patient observation period	Start and end dates
Demographics	Date of most recent contact with provider, date patient was diagnosed with a second primary malignancy
Performance assessments	Documented date, reported date
Secondary diagnoses	Diagnosis date
Progression, histology, lymphovascular invasion, metastatic sites, pancoast tumor, perineural invasion	Assessed date
Stage/TNM	Assessed date
Smoking	Assessed date

6.6.6. Context and rationale for follow up

Only intention-to-treat (ITT) analyses will be conducted. Although cross-over from the exposure to the comparator can be expected which biases the exposure treatment effect more towards the null, this also applies to the RCT. According to Slamon et al., although cross-over was not permitted during the study, a total of 399 (89.9%) patients in the palbociclib plus letrozole arm and 217 (97.7%) in the placebo plus letrozole arm discontinued treatment. 47 (11.8%) and 58 (26.7%) patients received a CDK4/6 inhibitor(s) poststudy, respectively; of these, the majority received palbociclib (74.5% in the palbociclib plus letrozole arm and 89.7% in the placebo plus letrozole arm, which would constitute a crossover).[6]

An as-treated analysis is not considered since in the context of oncology, reasons for discontinuation usually are due to toxicity, death or progression/non-response to the current treatment, all of which are highly correlated with the outcome under study which would hence lead to bias due to informative censoring.

6.6.7. Context and rationale for covariates

We identified a series of covariates that are strong prognostic factors for the outcome and auxiliary covariates which may be useful to impute missing data. Such covariates comprise demographics, covariates indicating disease-severity, cancer-specific covariates as well as pathological and genetic factors. In addition, selected labs and vitals are considered since they were shown to carry a high amount of prognostic information as described in Becker, Weberpals, et al.[10] For these variables, additional plausibility checks and transformations are carried out. In detail, labs and vitals are individually checked if they cross a certain biologically implausible threshold (e.g., a heart rate of 0) in which cases the values are set missing and imputed in a next step. These thresholds were compiled by experienced practicing physicians and medical oncologists and are listed in appendix **Table 9** and **Table 10**.

Note that not all covariates are available across all databases used for this trial emulation. In the analytical stage, the most comprehensive model will be fit for each database individually.

Table 5. Operational definitions of key covariates used for trial emulation.

Characteristic	Harmonized analysis variable name	R function to derive covariate (see pdf in appendix)	Details[1]	Variable encoding	Assessment window
Age at initial diagnosis	dem_age_initial_diagnosis	edbx_get_demographics()	Age measured at initial diagnosis of eligible primary tumor	Nominal (<60, 60-69, 70-79, 80+)	[-inf;0] at initial diagnosis of primary cancer
Age at index date	dem_age_index	edbx_get_demographics()	Age measured at index date	Binary (<60, 65+); modelled continuously in ROPRO[10]	[0;0]
Sex	dem_sex	edbx_get_demographics()	Sex	Binary (Male, Female)	[0;0]
Year of index date	c_year_index	De novo derived from dt_index	Calendar year in which patient initiated study treatment	Nominal (<2018, 2018+)	[0;0]
Family history	dem_family_history	edbx_get_demographics()	Family history of cancer	Logical (TRUE, FALSE)	[0;0] (no specific date is associated)
Race	dem_race	edbx_get_demographics()	Race categorized as in the original RCT	Binary (Asian vs non-Asian)	[0;0]

Characteristic	Harmonized analysis variable name	R function to derive covariate (see pdf in appendix)	Details[1]	Variable encoding	Assessment window
Ethnicity	dem_ethnicity	edbx_get_demographics()	Ethnicity	Hispanic, Non-Hispanic	[0;0]
Region	dem_region	edbx_get_demographics()	US region patient receives care in; if given on a state level, region is manually mapped (see **Table 11**)	Nominal (Northeast, South, West, Midwest)	[0;0]
Practice type	dem_practice	edbx_get_demographics()	Setting patient is receiving care at	Nominal (academic, community, academic & community)	[-inf;0]
Socio-economic status	dem_ses	edbx_get_demographics()	Socioeconomic status (SES) index based on residence area of patient	Nominal (from '1 - Lowest SES' through '5 - Highest SES)	[-inf;0]
Smoking	c_smoking_history	edbx_get_demographics()	History of current or former (= TRUE) or never (= FALSE) smoking on or anytime before index date; if there are multiple records per patient, any evidence of former/current smoking is prioritized	Binary logical (TRUE, FALSE)	[-inf;0]
PR status	c_pr_biomarker_status	edbx_get_biomarker()	Evidence of <u>any</u> PR mutation present. If patient has multiple measurements, any evidence of a mutation is prioritized. In case of ties, the closest measurement relative to index date is selected	Binary (negative, positive)	[-90;0]
ECOG	c_ecog	edbx_get_ecog()	ECOG performance status measured closest to index date within assessment window. In case of ties, the lower ECOG value is selected	Nominal (0, 1, 2, 3, 4); modelled as ordinal numeric in ROPRO[10]; due to I/E criteria ECOG is modelled as a binary (0, 1) covariate	[-90;0]
Stage	c_stage_initial_dx	edbx_get_diagnosis_solid()	AJCC summary group stage at initial diagnosis	Ordinal numeric (from 0 to IV with sub-categories, e.g., IA1)[10]	[-inf;0] at initial diagnosis of primary cancer
De novo metastatic status	c_de_novo_mets_dx	edbx_get_diagnosis_solid()	Evidence of presence of one or multiple metastases at/before initial diagnosis	Binary logical (TRUE, FALSE)	[-inf;0] at initial diagnosis of primary cancer

Characteristic	Harmonized analysis variable name	R function to derive covariate (see pdf in appendix)	Details[1]	Variable encoding	Assessment window
Evidence of metastases between initial diagnosis and index date	c_met_pre_index	edbx_get_diagnosis_solid()	Evidence of any metastasis between initial diagnosis and index date (includes the initial diagnosis and index date)	Binary logical (TRUE, FALSE)	[-initial dx;0]
Number of metastatic sites	c_number_met_sites	edbx_get_diagnosis_solid()	Number of metastatic sites for a given patient before/on index date	Integer	[-inf;0]
Time between initial diagnosis to index date	c_time_dx_to_index	edbx_get_diagnosis_solid()	Time in days between initial diagnosis to index date	Continuous	[-initial dx;0]
Time between earliest evidence of a metastatic and index date	c_time_met_dx_to_index	edbx_get_diagnosis_solid()	Time in days between earliest evidence of a metastatic and index date	Continuous	[-inf;0]
Histology (adenocarcinoma)	c_histology_match	edbx_get_histology()	Evidence of adenocarcinoma histology (non-squamous cell for EDB1)	Binary logical (TRUE, FALSE)	[-inf;0]
Albumin	c_albumin_g_l_cont	edbx_get_labs()	Closest albumin measurement (in serum/plasma) relative to index date in g/L. In case of ties, the lower is selected	continuous	[-90;0]
Alkaline phosphatase (ALP) [2]	c_alp_u_l_cont	edbx_get_labs()	Closest alkaline phosphatase measurement (in serum/plasma) relative to index date in U/L. In case of ties, the lower is selected	continuous	[-90;0]
Alanine aminotransferase (ALT) [2]	c_alt_u_l_cont	edbx_get_labs()	Closest alanine transaminase measurement (in serum/plasma) relative to index date in U/L. In case of ties, the lower is selected	continuous	[-90;0]
Aspartate aminotransferase (AST)	c_ast_u_l_cont	edbx_get_labs()	Closest aspartate aminotransferase measurement (in serum/plasma) relative to index date in U/L. In case of ties, the lower is selected. Used to compute AST-ALT ratio	continuous	[-90;0]
AST/ALT ratio	c_ast_alt_ratio_cont	edbx_get_labs()	AST/ALT ratio calculated from c_ast_u_l_cont/c_alt_u_l_cont	continuous	[-90;0]
Bilirubin[2]	c_bilirubin_mg_dl_cont	edbx_get_labs()	Closest bilirubin measurement (in serum/plasma) relative to index date in mg/dL. In case of ties, the lower is selected	continuous	[-90;0]

Characteristic	Harmonized analysis variable name	R function to derive covariate (see pdf in appendix)	Details[1]	Variable encoding	Assessment window
Calcium[2]	c_calcium_mg_dl_cont	edbx_get_labs()	Closest calcium measurement (in serum/plasma) relative to index date in mg/dL. In case of ties, the lower is selected	continuous	[-90;0]
Chloride	c_chloride_mmol_l_cont	edbx_get_labs()	Closest chloride measurement (in serum/plasma) relative to index date in mmol/L. In case of ties, the lower is selected	continuous	[-90;0]
Eosinophils/100 leukocytes[2]	c_eosinophils_leukocytes_ratio_cont	edbx_get_labs()	Eosinophils/100 leukocytes in blood. In case of ties, the lower	continuous	[-90;0]
Glucose[2]	c_glucose_mg_dl_cont	edbx_get_labs()	Closest glucose measurement (in serum/plasma) relative to index date in mmol/L. In case of ties, the lower is selected	continuous	[-90;0]
Granulocyte/leukocyte ratio [2]	c_granulocytes_leukocytes_ratio	edbx_get_labs()	Closest granulocyte/leukocyte ratio measurement (in blood) relative to index date. In case of ties, the lower is selected. Used to compute granulocyte/lymphocyte ratio	continuous	[-90;0]
Hemoglobin	c_hemoglobin_g_dl_cont	edbx_get_labs()	Closest hemoglobin measurement (in blood) relative to index date in g/L. In case of ties, the lower is selected	continuous	[-90;0]
Lactate dehydrogenase (LDH)[3]	c_ldh_u_l_cont	edbx_get_labs()	Closest LDH measurement (in serum or plasma) relative to index date in U/L. In case of ties, the lower is selected	continuous	[-90;0]
Lymphocytes	c_lymphocyte_10_9_l_cont	edbx_get_labs()	Closest lymphocytes measurement (in blood) relative to index date in 10^9/L. In case of ties, the lower is selected. Used to compute neutrophil/lymphocyte ratio	continuous	[-90;0]
Lymphocyte/leukocyte ratio[2]	c_lymphocyte_leukocyte_ratio_cont	edbx_get_labs()	Closest lymphocyte/leukocyte ratio measurement (in blood) relative to index date. In case of ties, the lower is selected. Used to compute neutrophil/lymphocyte ratio	continuous	[-90;0]

Characteristic	Harmonized analysis variable name	R function to derive covariate (see pdf in appendix)	Details[1]	Variable encoding	Assessment window
Monocytes[2]	c_monocytes_10_9_l_cont	edbx_get_labs()	Closest monocytes measurement (in blood) relative to index date in 10^9/L. In case of ties, the lower is selected.	continuous	[-90;0]
Neutrophils	c_neutrophil_10_9_l_cont	edbx_get_labs()	Closest neutrophils measurement (in blood) relative to index date in 10^9/L. In case of ties, the lower is selected. Used to compute neutrophil/lymphocyte (NLR) ratio	continuous	[-90;0]
Neutrophil/lymphocyte ratio[2]	c_neutrophil_lymphocyte_ratio_cont	edbx_get_labs()	Neutrophil/lymphocyte (NLR) ratio calculated from c_neutrophil_10_9_l_cont/ c_lymphocyte_10_9_l_cont	continuous	[-90;0]
Platelets	c_platelets_10_9_l_cont	edbx_get_labs()	Closest platelets measurement (in blood) relative to index date in 10^9/L. In case of ties, the lower is selected	continuous	[-90;0]
Protein	c_protein_g_l_cont	edbx_get_labs()	Closest protein measurement (in serum/plasma) relative to index date in g/L. In case of ties, the lower is selected	continuous	[-90;0]
Urea nitrogen[2]	c_urea_nitrogen_mg_dl_cont	edbx_get_labs()	Closest urea nitrogen measurement (in serum/plasma) relative to index date in mg/L. In case of ties, the lower is selected	continuous	[-90;0]
Systolic blood pressure[2]	c_sbp_cont	edbx_get_vitals()	Closest systolic blood pressure (in mmHg) measurement. In case of ties, the lower is selected	continuous	[-90;0]
Body mass index (BMI)[2]	c_bmi_cont	edbx_get_vitals()	Closest BMI measurement (in kg/m2) relative to index date. In case of ties, the lower is selected.	continuous	[-90;0]
Heart rate[2]	c_hr_cont	edbx_get_vitals()	Closest heart rate measurement (in bpm) relative to index date. In case of ties, the lower is selected	continuous	[-90;0]
Oxygen saturation	c_oxygen_cont	edbx_get_vitals()	Closest heart rate measurement (in bpm) relative to index date. In case of ties, the lower is selected	continuous	[-90;0]

[1] x stands for the pseudonymized number of the respective database, i.e., EDB1, EDB3 or EDB4

[2] For calculation of ROPRO prognostic score[10], this variable is log transformed.

[3] For calculation of ROPRO prognostic score[10], this variable is log-log transformed.

6.7. Data analysis

6.7.1. Context and rationale for analysis plan

To emulate the PALOMA-2 trial, the following analytical workflow will be used (Figure 2). First, an analytical cohort with covariates on key eligibility criteria and prognostic factors will be derived across all databases. To ensure reproducibility and consistency throughout the entire ENCORE project, the internally developed *encore.io* R package streamlines this process using the functions referenced in Table 5. Operational definitions of key covariates used for trial emulation. Table 5 (code documentation see appendix).[15] The analytical cohort will be derived by first identifying a metastatic breast cancer inception cohort of initiators of palbociclib plus letrozole or letrozole alone in the first-line setting as described in section 6.6.4. Next, key eligibility criteria will be applied in which patients with missing values are considered eligible in the respective attrition steps to allow thorough missing data investigations.

Figure 2. Illustration of principled analytical workflow.
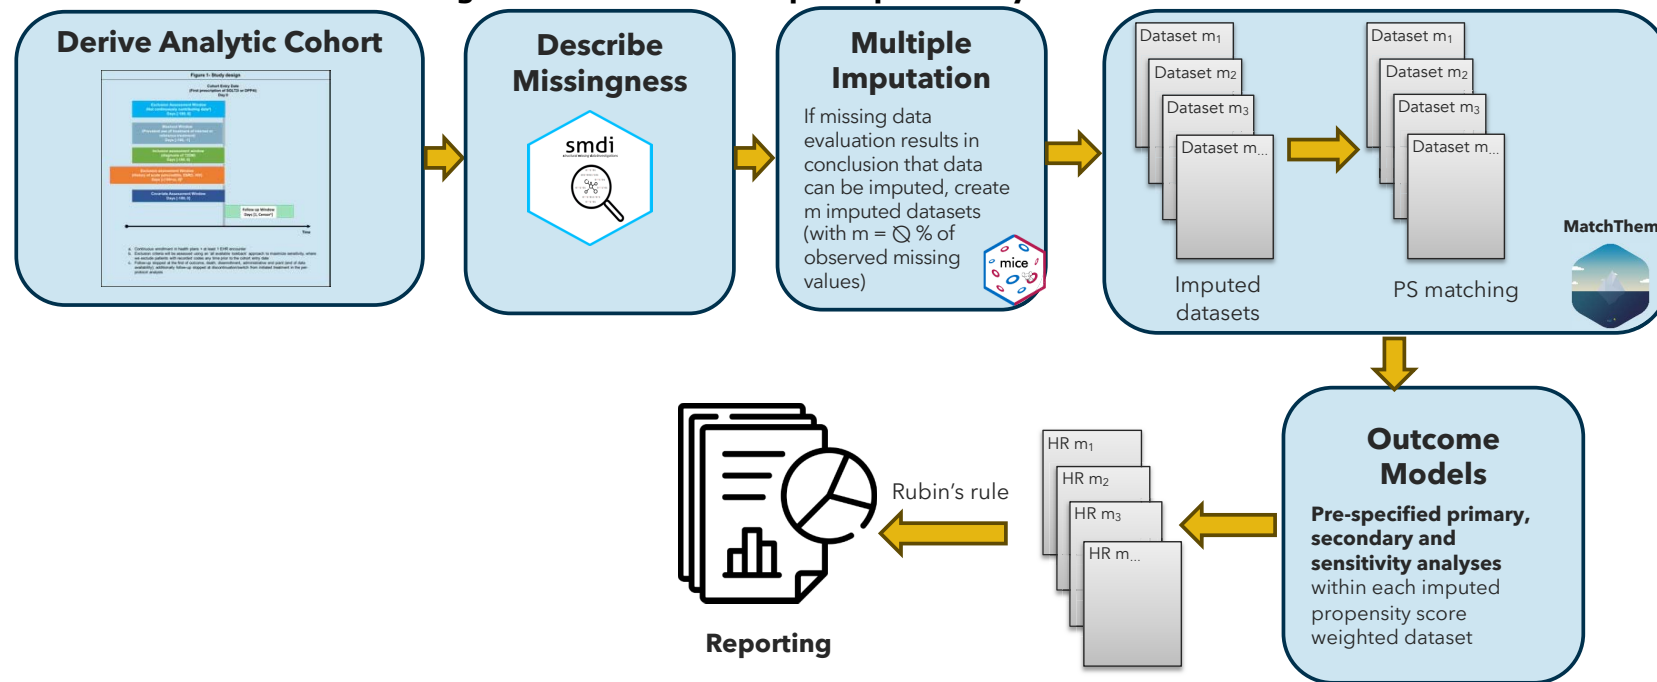

Once a full analytic cohort is built, principled missing data investigations will be employed to empirically assess assumptions on potentially underlying missingness mechanisms according to Rubin's classification of missing data (i.e., missing completely at random [MCAR], missing at random [MAR] and missing not at random [MNAR]).[16] To that end, we will adopt a principled process on missing data that was developed as part of a FDA Sentinel Innovation Center causal inference workstream that empirically evaluates different aspects across partially observed covariates based on three group diagnostics (Table 6).[17,18] In brief, the first group diagnostics computes distributions and absolute standardized mean differences (ASMD) between patients with and without an observed value for a given partially observed covariates. If missingness can be explained by observed covariates such as in MAR mechanisms, patient characteristics will significantly differ which will (in

analogy to propensity scores) be indicated by ASMDs > 0.1. In addition, Hoteling's[19] and Little's[20] tests additionally provide formal hypothesis tests for such comparisons in which high test statistics and a rejection of the null hypothesis would provide evidence for differences in the distribution of patient characteristics and suggest the underlying mechanism is not MCAR or MNAR. Group 2 diagnostics assess the ability to predict missingness based on observed covariates by fitting a classification model to predict the missingness indicator of the partially observed covariate. To that end, we will fit a random forest (RF) classification model using observed covariates with a 70/30 train-test split of the complete cohort. A sufficiently high area under the receiver operating characteristic curve (AUC) metric of the test dataset may demonstrate that missingness can be predicted well and could point towards MAR as a likely mechanism as opposed to an AUC~0.5 which would suggest MCAR or MNAR. Group 3 diagnostics evaluates the association between the missingness indicator of the partially observed covariates and the outcome (OS). If the missingness of a confounder cannot be explained or approximated by observed covariates and a difference in the outcome is observed depending on the missingness indicator (e.g., $HR_{\text{missingness indicator}} \neq 1$), this may be indicative of an underlying MNAR mechanism. These empirical diagnostics will be implemented through the smdi R package[21] and be further enhanced by clinical expert knowledge.

**Table 6. Diagnostics to empirically differentiate and characterize missing data mechanisms.**

	Group 1 Diagnostics		Group 2 Diagnostics	Group 3 Diagnostics
Diagnostic metric	Absolute standardized mean difference (ASMD)	P-value Hoteling[19] Little[20]	Area under the receiver operating curve (AUC)	Log HR (missingness indicator)
Purpose	Comparison of distributions between patients with vs. without observed value of the partially observed covariate.		Assessing the ability to predict missingness based on observed covariates.	Check whether missingness of a covariate is associated with the outcome (differential missingness).
Example value	ASMD = 0.1	p-value < 0.001	AUC = 0.5	log HR = 0.1 (0.05 to 0.2)
Interpretation	<0.1[a]: no imbalances in observed patient characteristics; missingness may be likely completely at random or not at random (~MCAR, ~MNAR). >0.1[a]: imbalances in observed patient characteristics; missingness may be likely at random (~MAR).	High test statistics and low p-values indicate differences in baseline covariate distributions and null hypothesis would be rejected (~MAR).	AUC values ~ 0.5 indicate completely random or not at random prediction (~MCAR, ~MNAR). Values meaningfully above 0.5 indicate stronger relationships between covariates and missingness (~MAR).	No association in either univariate or adjusted model and no meaningful difference in the log HR after full adjustment (~MCAR). Association in univariate but not fully adjusted model (~MAR). Meaningful difference in the log HR also after full adjustment (~MNAR).

Abbreviations: ASMD = Median absolute standardized mean difference across all covariates, AUC = Area under the curve, CI = Confidence interval, MAR = Missing at random mechanism in which the missingness probability depends on observed covariates, MCAR = Missing completely at random mechanism in which each patients has the same missingness probability, MNAR(unmeasured) = Missing not at random mechanism in which the missingness can only be explained by a covariate which is not observed in the underlying dataset, MNAR(value) = Missing not at random mechanism in which the missingness just depends on the actual value of the partially observed confounder of interest itself.

[a] Analogous to propensity score-based balance measures.[22]

While the MAR assumption is a strong assumption to hold across all considered covariates, it was shown that especially in the context of partially observed covariate data (as opposed to missing exposure and outcome data), only mechanisms in which a covariate causes its own missingness leads to critical bias (MNAR).[23,24] In such situations, multiple imputation can have significant advantages over a complete case analysis since additional information (auxiliary covariates and missing indicator variables) can be included in imputation algorithms which can make the MAR assumption holding more plausible and increase efficiency in treatment effect estimates since all patients and critical covariates can be retained and variances can be realistically estimated, considering both the general sampling error and the error introduced by missing data.[25,26] Hence, multiple imputation with flexible, non-parametric random forest imputation algorithms[27] (mice R package[28]) will be used for this trial emulation. The number of imputed datasets (m) will be determined for each database separately based on the average proportion missingness observed in the analytic cohort and results from the above-referenced missing data investigations will inform the choice of appropriate sensitivity analyses.

Figure 3. Covariate balance across imputed datasets (simulated example).
To estimate the treatment effects for palbociclib plus letrozole using propensity score matching across imputed datasets we will apply the "within" approach using the "MatchThem" R package.[29,30] That is, propensity score matching and the estimation of the treatment effect are performed in each imputed dataset separately and resulting treatment effect estimates are combined using Rubin's rule. In this study, this will be implemented by matching eligible patients on their propensity to initiate palbociclib plus letrozole using a 1:1 nearest neighbor matching algorithm without replacement and a caliper of 1% of the standard deviation of the propensity score. The resulting covariates balance will be assessed by computing and visualizing ASMDs before and after matching across datasets. As compared to a single dataset matching approach, this can lead to a range of ASMDs per covariate due to random variation across imputed datasets for which an example (using simulated data) is illustrated in Figure 3. If sufficient balance can be established, a Cox proportional hazards regression model will be fit to estimate the marginal average treatment effect in the matched population. Since in most databases there are more palbociclib-plus-letrozole patients than patients in the control arm, the estimand will rather correspond to the ATC than the ATT. Confidence intervals will be estimated using cluster-robust standard errors.[31] As a secondary endpoint, we will additionally estimate the median OS survival time difference between the two exposure groups using the Kaplan-Meier method. It should be noted that due to administrative and de-identification purposes, the date of death is often only available at the month- or year-granularity level, in which case the date of death will be imputed to the 15th of a month or July 2nd of a year, respectively (depending on the database). In rare cases, this can lead to negative/implausible follow-up times if the date of death is very close to the index date. These patients will be excluded from the analysis.

The final hazard ratio and median OS survival time difference estimates for each database will then be combined using Rubin's rule.[28,32] To arrive at a single estimate across databases, the final estimates will be summarized through a meta-analytic fixed effects model.[33] A summary of the analytic approach is summarized in Table 7 and an example workflow with simulated data and annotated code can be found here.

A. Primary analysis

Table 7. Primary, secondary, and subgroup analysis specification

Hypothesis:	Initiation of palbociclib plus letrozole decreases the hazard of all-cause mortality as compared to initiation of letrozole alone
Exposure contrast:	Initiation of palbociclib plus letrozole vs letrozole alone
Primary outcome:	Time to all-cause mortality (OS)
Secondary outcome:	Time-to-next-treatment (TTNT) defined as a composite outcome of all-cause mortality or adding or switching to a second-line treatment.[34,35]
Databases used:	EDB1, EDB3, EDB4
Time period:	From 2015 (approval year for palbociclib) - 2022 (publication of OS outcome for competitor ribociclib)[36]
Analytic software:	R 4.3.2. Version control of code and R packages will be established through git and Posit package manager, respectively. All packages are frozen to their most recent version as of April 24, 2024.
Model(s): *(provide details or code)*	See example code here. The annotated code for the trial emulation will be hosted at https://drugepi.gitlab-pages.partners.org/encore/paloma2-nct-01740427/ (access only through MGB network for authorized personnel)
Confounding adjustment method	*Name method and provide relevant details, e.g. bivariate, multivariable, propensity score matching (specify matching algorithm ratio and caliper), propensity score weighting (specify weight formula, trimming, truncation), propensity score stratification (specify strata definition), other.*
	1:1 propensity score nearest neighbor matching without replacement and a caliper of 1% of propensity score standard deviation
Missing data methods	*Name method and provide relevant details, e.g. missing indicators, complete case, last value carried forward, multiple imputation (specify model/variables), other.*
	Multiple imputation by chained equations using a random forest imputation model across all covariate types. The number of imputed datasets will be determined by the average proportion of missing values across all partially observed covariates. Imputation models will include all variables of the substantiative model, i.e., exposure, outcome, confounders/prognostic factors and additional auxiliary covariates.
Subgroup Analyses	*List all subgroups*
	In subgroup analysis, multiple imputation, propensity score matching and balance assessment will be conducted within each subgroup separately. The treatment effect will be estimated for each stratum separately (stratum-specific effects). 1. Age (<65, ≥65) 2. Region (North America, Europe, Asia/Pacific) 3. ECOG (0, 1) 4. Disease-free interval (De-novo metastatic, ≤12 months, >12 months) According to Slamon et al,[6] the subgroup analyses are considered exploratory in nature and performed with no formal statistical testing.

Table 8. Sensitivity analyses – rationale, strengths and limitations.

	What is being varied? How?	Why? (What do you expect to learn?)	Strengths of the sensitivity analysis compared to the primary	Limitations of the sensitivity analysis compared to the primary
Sensitivity #1	Caliper matching on ROPRO prognostic score instead of propensity score	Matching patients on validated prognostic score may be more beneficial to control for (unmeasured) confounding	Matches patients on validated prognostic score that incorporates weights of key prognostic factors	Limited experience on how to optimally use prognostic scores and should be seen as an <u>experimental</u> sensitivity analysis
Sensitivity #2	ATO weighting instead of matching	Weights that resemble the average treatment effect in the overlap population (ATO) create a clinical equipoise population which is comparable to an RCT	ATO weighting usually results in excellent balance and clinical equipoise	Estimates the average treatment effect among the overlap patients which may not be comparable to target population anymore
Sensitivity #3	SMR/ATT weighting instead of matching. Here symmetric trimming (i.e., setting all weights lower/higher than that at a given quantile to the weight at the quantile) of extreme weights may be considered with the quantiles chosen based on weight distribution and resulting balancing performance.	SMR weighting retains all patients and resembles the same estimand as matching	ATT weighting retains all patients	Patients with extreme weights after trimming may bias the analysis
Sensitivity #4	Censoring date is changed to 3 months before data cut-off date	For all databases, information on mortality comes from different data sources which are updated asynchronously. To account for the potential lag of updated mortality information (*ghost-time bias*[37]), the censoring for patients without mortality event in the whole patient identification period will be moved to last sign of patients being alive/visit or 3 months before data cut-off date, whichever occurred earlier.[38]	Approach implements a more conservative censoring rule	Approach addresses ghost-time bias by censoring patients without a recorded death event earlier
Sensitivity #5	Delta imputation models for MNAR (tipping point analysis)	Primary multiple imputation analysis assumes MAR which	Estimates impact of deviations from MAR assumption on final	Delta parameters must be assumed and results are complex to interpret in

	may not hold for every covariate	treatment effect estimates for key covariates	multivariate missingness settings; just most important covariates or those with highest suspicion of being MNAR will be evaluated
Sensitivity #6	Re-weighting of strong risk factors and/or treatment effect modifiers distribution to match that of PALOMA-2	In the presence of effect modification, treatment effect estimates may be different if the distribution of strong risk factors/effect modifiers is different in the emulated cohort versus the trial cohort	Re-weighting adjusts for differences in distributions of key risk factors and/or treatment effect modifiers (see subgroup analysis in Table 7)	Re-weighting risk factors/potential effect modifiers to match the PALOMA-2 trial and simultaneously balancing them across treatment groups may be challenging due to differences in measurement
Sensitivity #7	Including patients who have had at least 1 visit 90 days prior to treatment initiation	EHR are often lacking data continuity, and this analysis uses the requirement of 1 visit as a proxy for continuous observation periods	Considers aspect of data continuity	There may be patients who are put on treatment immediately in which case they are falsely excluded
Sensitivity #8	Using all available calendar time	This analysis explores potential confounding related to calendar time, evolving clinical practice patterns, and access to therapies.	Aims to assess the extent of confounding introduced by changes in time, treatment practices, and access to therapies.	We expect the results to be more confounded due to calendar time.
Sensitivity #9	Missingness is handled by restricting to patients with complete observations on a subset of the most important confounders ("complete cases").	Instead of imputing data, this sensitivity analysis restricts the analysis cohort to patients with complete observations on key confounders	Data will not be imputed and missingness is assumed to be missing completely at random	The restriction to complete cases will significantly decrease sample size. To limit the attrition of patients with partially observed covariates, it won't be possible to use all covariates used in the main analysis propensity score model, but only consider key covariates with overall low proportions of missingness (age, sex, etc.)
Sensitivity #10	Exclusion of patients with >1 year between metastasis diagnosis and index date	This sensitivity analysis varies the inclusion criteria by excluding patients whose index date (treatment start) is >1 year after their metastatic diagnosis date which is	Helps ensure that treatment reflects initial first-line treatment of metastatic disease, not late-line therapy.	Exclusion of further patients results in a smaller cohort size which may reduce statistical power.

	clinically unrealistic or implausible for a first-line treatment

6.8. Study size and feasibility

See appendix 4 (first feasibility matching on age, sex, comorbidity score) and appendix 5 (second feasibility matching on all predefined propensity score variables). Propensity score distribution plots with c-statistics are available in appendix 6. Table 1 showing prevalence of baseline characteristics and standardized differences in distribution are available in appendix 7.

7. Limitation of the methods

- Missingness in prognostic factors is a major challenge which is addressed in this emulation by multiple imputation using a non-parametric imputation algorithm. Multiple imputation usually assumes that missingness can be explained by observed characteristics, which may be empirically evaluated using principled missingness diagnostics, but the true underlying missingness mechanisms are usually unknown. Nevertheless, multiple imputation makes use of additional information (auxiliary covariates) which can render the underlying missingness assumptions more plausible. In addition, assumptions for alternative missing data approaches like complete case analysis or the "missing indicator approach" come with even stronger assumptions and additionally have the limitation of significantly reduced sample sizes, especially when comprehensively adjusting for known confounders and prognostic factors.

- Data continuity is a major challenge in EHR databases since "guaranteed" observable periods (such as continuous enrolment periods in administrative claims data) do not exist which may lead to measurement error in key covariates and exposure misclassification. Sensitivity analysis #7 tries to address this requiring patients to have had at least one visit before the index date which increases the likelihood that a patients was not only diagnosed at the respective center but is also regularly seen.

- Balancing patients on calendar year is not possible since calendar year shows instrumental variable-like behaviours (see Figure 12), i.e., it perfectly predicts treatment assignment and does not have any association with the outcome other than through the exposure. This assumption is formally untestable but clinically reasonable since there has not been any other significant change in treatment paradigms for PALOMA-2--like postmenopausal, ER-positive, HER2-negative metastatic breast cancer populations other than introduction of palbociclib plus letrozole. The improvements of radiation of brain metastases may be the only exception, but it is expected that this may be of negligible significance for the scope of this emulation.

8. Protection of human subjects

This study has been approved by the Brigham and Women's Hospital Institutional Review Board.

10. Appendices

10.1. CONSORT diagrams

The following CONSORT attrition diagrams depict the process to select eligible PALOMA-2-like populations in EDB1, EDB3 and EDB4 for the main analysis, respectively.

**Figure 4. CONSORT attrition to select eligible PALOMA-2-like populations in EDB1.**

Figure 5. CONSORT attrition to select eligible PALOMA-2-like populations in EDB3.
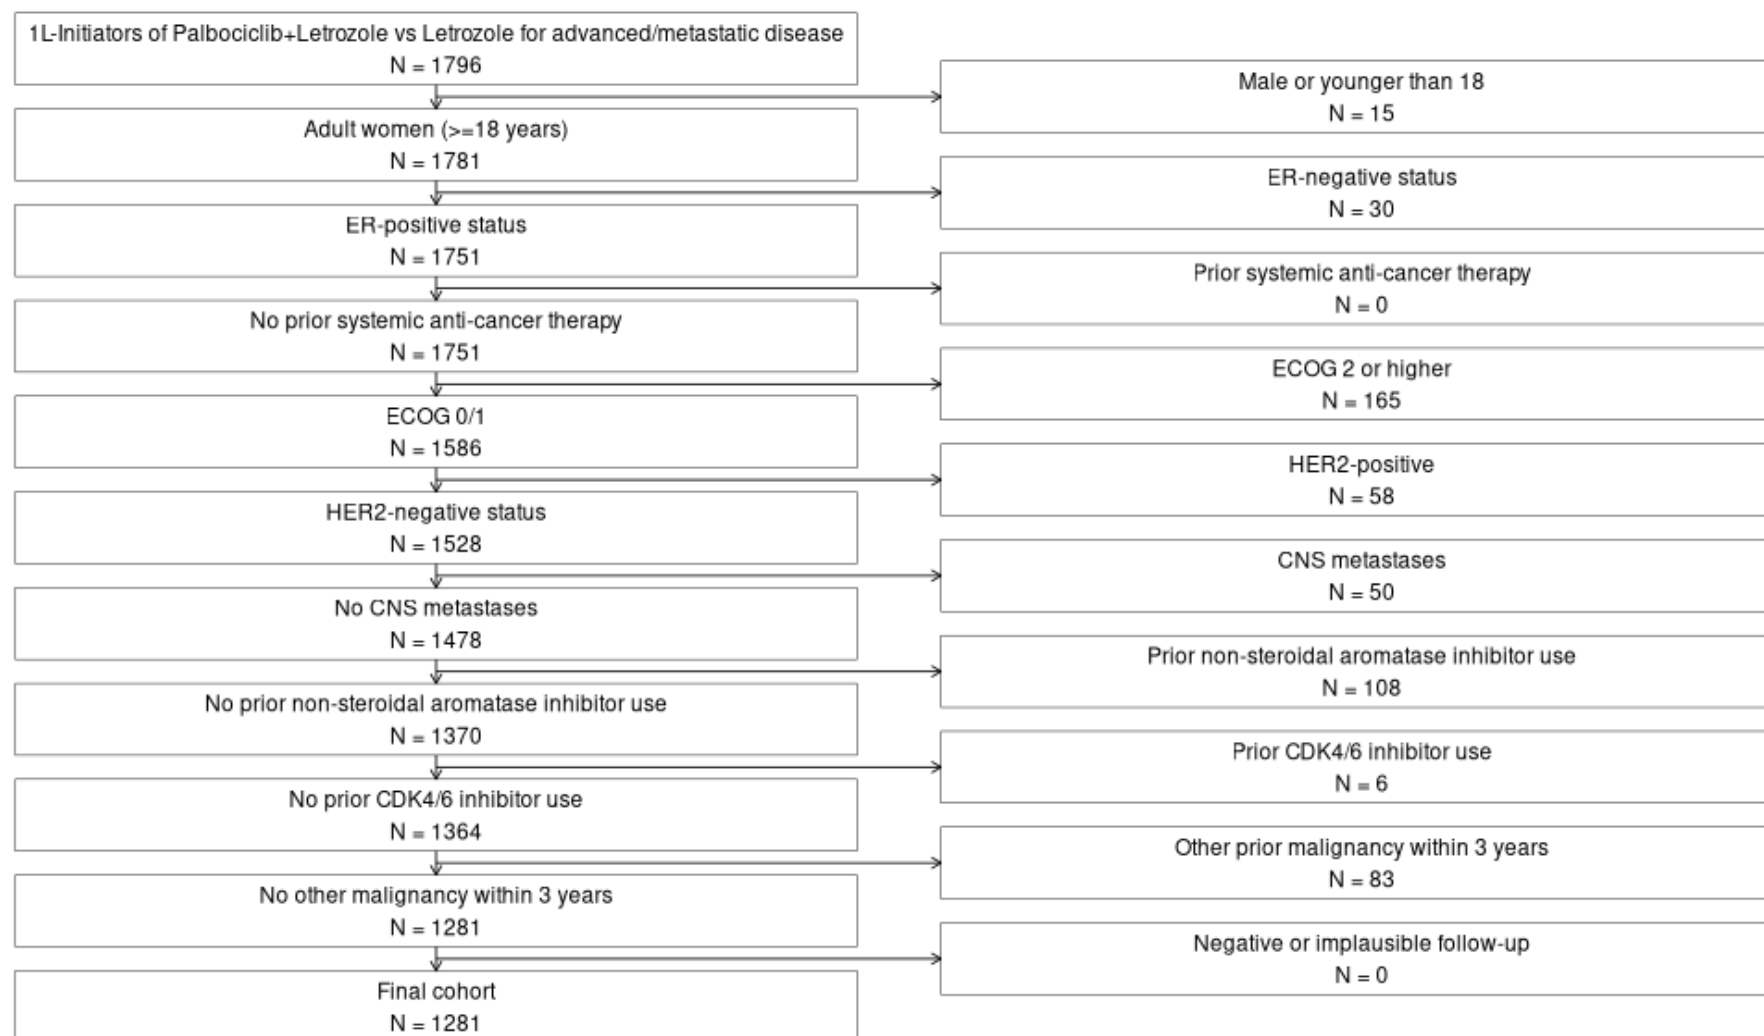

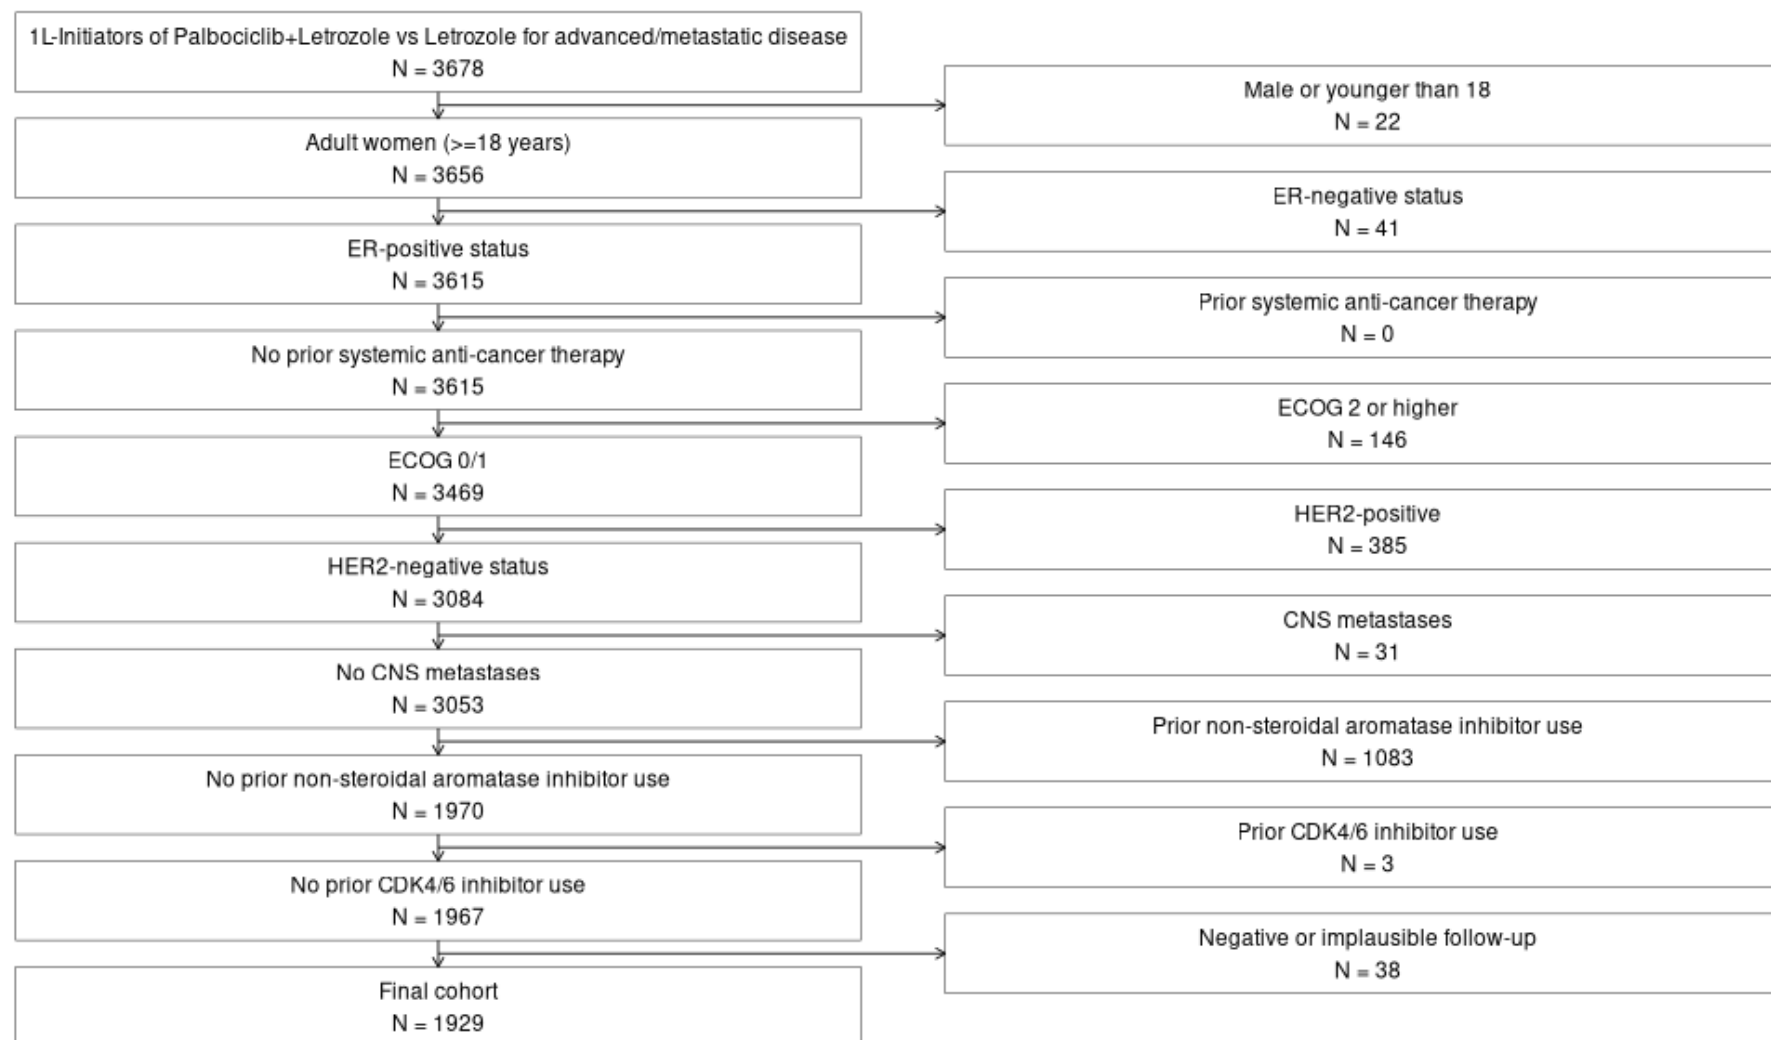

edb3 attrition

Main flow	Excluded
1L-Initiators of Palbociclib+Letrozole vs Letrozole for advanced/metastatic disease N = 1796	
	Male or younger than 18 N = 15
Adult women (>=18 years) N = 1781	
	ER-negative status N = 30
ER-positive status N = 1751	
	Prior systemic anti-cancer therapy N = 0
No prior systemic anti-cancer therapy N = 1751	
	ECOG 2 or higher N = 165
ECOG 0/1 N = 1586	
	HER2-positive N = 58
HER2-negative status N = 1528	
	CNS metastases N = 50
No CNS metastases N = 1478	
	Prior non-steroidal aromatase inhibitor use N = 108
No prior non-steroidal aromatase inhibitor use N = 1370	
	Prior CDK4/6 inhibitor use N = 6
No prior CDK4/6 inhibitor use N = 1364	
	Other prior malignancy within 3 years N = 83
No other malignancy within 3 years N = 1281	
	Negative or implausible follow-up N = 0
Final cohort N = 1281	

Figure 6. CONSORT attrition to select eligible PALOMA-2-like populations in EDB4.

edb4 attrition

1L-Initiators of Palbociclib+Letrozole vs Letrozole for advanced/metastatic disease N = 3678	Male or younger than 18 N = 22
Adult women (>=18 years) N = 3656	ER-negative status N = 41
ER-positive status N = 3615	Prior systemic anti-cancer therapy N = 0
No prior systemic anti-cancer therapy N = 3615	ECOG 2 or higher N = 146
ECOG 0/1 N = 3469	HER2-positive N = 385
HER2-negative status N = 3084	CNS metastases N = 31
No CNS metastases N = 3053	Prior non-steroidal aromatase inhibitor use N = 1083
No prior non-steroidal aromatase inhibitor use N = 1970	Prior CDK4/6 inhibitor use N = 3
No prior CDK4/6 inhibitor use N = 1967	Negative or implausible follow-up N = 38
Final cohort N = 1929	

10.2. Covariate balance figures

The following figures illustrate the balance of key covariates included in propensity score models among eligible PALOMA-2-like populations in EDB1, EDB3 and EDB4, respectively.

Figure 7. EDB1 covariate balance of covariates included in propensity score model before and after matching.
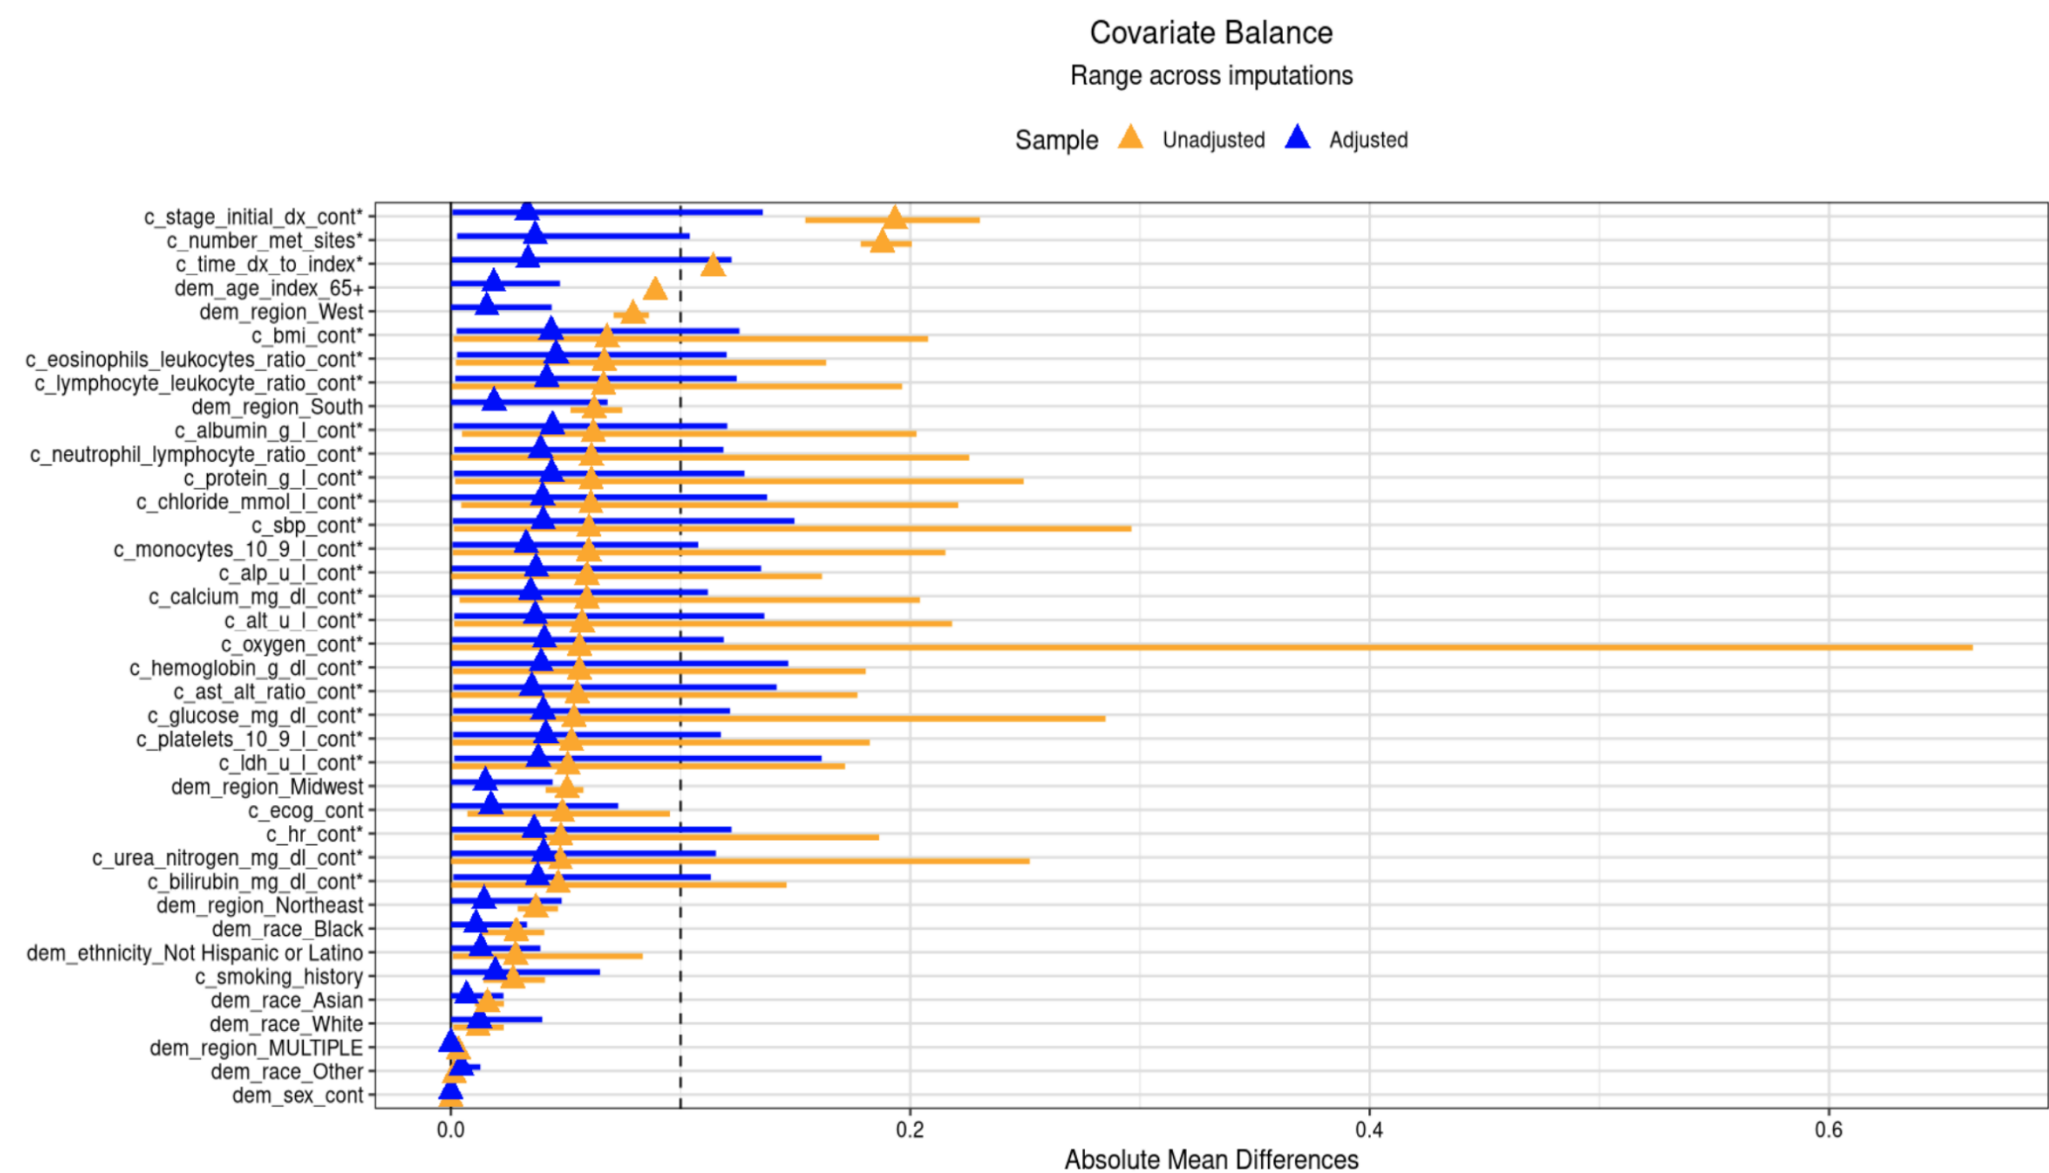

Figure 8. EDB3 covariate balance of covariates included in propensity score model before and after matching.

Figure 9. EDB4 covariate balance of covariates included in propensity score model before and after matching.

Covariate Balance
Range across imputations

Sample △ Unadjusted △ Adjusted

10.3. Sample size/power calculations

Power estimations are computed based on the average number of observed events across imputed and matched datasets according to the methodology described by Schoenfeld.[39] The OS result was null in the trial, therefore, we are not expecting to observe a strong effect in the emulation. Because our sample sizes are larger than the number of trial participants (2887 in EDB1, 1281 in EDB3, and 1929 in EDB4 vs 666 in the trial), we expect our confidence intervals to be narrower.

**Figure 10a. Number of events needed to achieve x% power for overall-survival outcome**

Figure 11b. Number of events needed to achieve x% power for progression-free-survival / time-to-next-treatment outcome

Assuming alpha = 0.05, 50% exposed and HR = 0.58

10.4. Additional Figures and Tables

Table 9. Lab measurement plausibility thresholds.

Lab and standardized unit	Lower plausibility threshold	Upper plausibility threshold

c_albumin_g_l	10	200
