2.0 STUDY SCHEMA

3.0 STUDY SYNOPSIS

3.1 Study Objectives

CTN-0080 includes four objectives:

- Primary Objective: To evaluate the impact of treating opioid use disorder (OUD) in pregnant women with extended-release (XR) buprenorphine (BUP), compared to sublingual (SL) BUP, on mother and infant outcomes. Hypothesized outcomes are that the BUP-XR, relative to the BUP-SL, group will:
 - 1) not have greater illicit opioid use during pregnancy (primary, non-inferiority);
 - 2) have lower infant neonatal opioid withdrawal syndrome (NOWS) severity (key secondary, superiority); and
 - 3) not have greater postpartum illicit opioid use (key secondary, non-inferiority).
- Secondary Objective: To test conceptual models of the mechanisms by which BUP-XR may improve mother-infant outcomes, relative to BUP-SL.
- Tertiary Objective: To determine the economic value of utilizing BUP-XR, relative to BUP-SL, to treat pregnant women.
- Quaternary Objective: To evaluate the impact of BUP-XR, relative to BUP-SL, on infant neurodevelopment.

3.2 Study Design

This is an intent-to-treat, two-arm, open-label, pragmatic randomized controlled trial. Eligible participants will be randomized in a 1:1 ratio to BUP-XR or BUP-SL, balancing on site, estimated gestational age (EGA) at time of randomization (6 weeks-18 weeks vs. 19 weeks-30 weeks), and whether they are on BUP-SL at the time of randomization (yes vs. no). Participants will be provided with study medication and attend weekly medication visits through 12 months postpartum. Participants will be invited to participate in the conceptual model assessment (CMA) sub-study, which will be used to evaluate the MOMs conceptual models. Infant caregivers will be invited to participate in the infant neurodevelopmental outcomes (INO) sub-study, which will include a 24-month child assessment. The INO data will be locked separately from the rest of the CTN-0080 database to allow CTN-0080 database lock following collection of the final (non-INO) CTN-0080 data point.

3.3 Study Population

Approximately 200 pregnant women, recruited from approximately 10 sites, will be randomized into the trial. Sites that provide BUP to pregnant women in an office-based setting, offer BUP treatment following delivery for ≥ 12 months, and admit enough potentially eligible women to meet the target randomization rate (1.25 per month) are eligible. The study population will include pregnant women who have an EGA of 6-30 weeks at randomization, and, in the judgment of the treating provider, are good candidates for BUP-maintenance treatment. All randomized participants will be encouraged to participate in the CMA and INO sub-studies.

3.4 Treatments

Participants randomized to BUP-XR will receive a weekly formulation of CAM2038 during pregnancy. During the 12-month postpartum phase, women who are breastfeeding will continue

receiving BUP-XR weekly while women who are not breastfeeding will receive monthly BUP-XR. Participants randomized to BUP-SL will receive buprenorphine, with or without naloxone, based on site preference, during pregnancy and the 12-month postpartum phase.

3.5 Assessments

The primary outcome is illicit opioid abstinence during pregnancy, assessed by urine drug screens (UDSs). Key secondary outcomes for the primary objective are infant NOWS severity assessed by total days of opioid treatment (derived from medical records), and mother postpartum illicit opioid abstinence assessed by UDSs. The CMA sub-study includes assessments of: 1) maternal trough BUP plasma concentrations at study weeks 3 and 5; 2) fetal non-stress test and biophysical profile at ~36 weeks EGA at maternal peak BUP plasma level; 3) maternal peak and trough BUP plasma concentrations at ~36 weeks EGA; and 4) cord and maternal plasma BUP/BUP-metabolite levels at delivery. The main economic outcome will be the incremental cost-effectiveness ratio (ICER). The main neurodevelopmental outcome of the INO sub-study will be the cognitive subscale of the Bayley Scales of Infant and Toddler Development™, Fourth Edition (Bayley™-4) when the child is approximately 24 months of age.

Study assessments will ideally occur at the clinic site; however, as needed these visits may occur in whole or in part via telemedicine, at other institutionally-affiliated clinical sites, or elsewhere in the community (including, but not limited to, home visits, visits at other non-affiliated clinical/laboratory sites, or other community sites affording appropriate safety and confidentiality) as permitted by the institution and other regulatory bodies. For the CMA and INO sub-studies, it is likely that some study procedures will occur outside the clinic at locations deemed most appropriate by the providers performing the study assessments (including, but not limited to, the delivery hospital, an external laboratory, or other clinical location).

3.6 Primary Analysis

A Type-I error rate of $\alpha=.025$ will be used for the non-inferiority primary outcome analysis.

4.0 BACKGROUND AND RATIONALE

4.1 Background

4.1.1 Introduction

The growing opioid-use epidemic in the U.S. has been associated with a significant increase in the prevalence of pregnant women with opioid use disorder (OUD)¹⁻⁴ and neonatal abstinence syndrome (NAS)/neonatal opioid withdrawal syndrome (NOWS).^{5, 6} NAS/NOWS is associated with adverse health effects for the infant⁷⁻⁹ and with costly hospitalizations.⁶ In 2012, the average length of stay (LOS) for NAS/NOWS was 16.9 days and the average cost was \$66,700.⁶ In 2013, about 4% of total neonatal intensive care unit days were attributed to infants with NAS/NOWS, compared to just 0.6% in 2004.¹⁰ The American College of Obstetricians and Gynecologists (ACOG) Committee, together with the American Society of Addiction Medicine, published their recommendation in 2012 that opioid-dependent pregnant women should not be tapered off opioids and should be treated with methadone or, possibly, buprenorphine (BUP).¹¹ A more definitive recommendation for either methadone or BUP treatment was made by the World Health Organization in 2014.¹² This opinion has been maintained based on more recent literature reviews,¹³ and the relative advantages/disadvantages of each treatment approach have been further delineated. Relative to methadone, BUP offers the advantages of greater convenience for pregnant women and lower NAS/NOWS severity in their infants.¹⁴ Some disadvantages of BUP include increased risk of diversion,¹⁵ poorer adherence,¹⁵ greater treatment dropout,¹⁶⁻¹⁸ and daily peak-trough effects.¹⁹ While applicable to individuals with OUD in general, these disadvantages may be more pronounced in pregnant women.

4.1.2 Treatment Adherence and Retention

Pregnant women with OUD face a number of challenges, including psychosocial stressors and psychiatric co-morbidity that may serve to reduce medication adherence.²⁰ In addition, because the most common concerns of BUP-maintained pregnant women are the health of their unborn infants and the potential for NAS/NOWS,²¹ expecting 100% adherence to daily self-administration of a medication that a woman worries may harm her unborn infant may be unrealistic. While the reasons are not entirely clear, treatment retention in BUP-maintained pregnant women is problematic, with retention rates estimated to be 57.7% compared to retention rates of 78.1% for methadone treatment.¹⁴ In SAMHSA's 2018 clinical guidance,¹³ it was noted that the postpartum period is a time when women are particularly vulnerable for relapse and an increased risk of overdose during the postpartum phase has been documented.²² Hence, receiving effective treatment during the postpartum period is of critical importance. The limited research on postpartum retention in opioid maintenance treatment has found dropout rates of up to 36% by 3 months postpartum and 62% by 6 months postpartum.²³ The high dropout rates are perhaps not surprising given the demands that motherhood entails, which likely serve to make daily medication adherence and treatment attendance more difficult.

4.1.3 Daily Peak-Trough Effects

In individuals with OUD, the daily BUP-SL trough is problematic in that plasma levels may be insufficient for suppressing opioid withdrawal symptoms.¹⁹ In pregnant women, both the BUP-SL peak and trough may be problematic. For the fetus, the BUP-SL peak is associated with adverse effects, including decreased fetal heart rate and heart rate variability.²⁴ Problems with BUP-SL trough are likely exacerbated in pregnant women, relative to non-pregnant individuals, since BUP is cleared more rapidly during pregnancy.^{25, 26} Research suggests that BUP plasma concentrations ≥ 1 ng/mL are required to suppress opioid withdrawal symptoms²⁷ and, thus, BUP-

SL should be dosed to maintain individuals at ≥ 1 ng/mL throughout the dosing cycle.¹⁹ Modeling studies suggest that plasma concentrations of 2-3 ng/mL are required for opioid blockade;^{19, 28} however, analysis of a recent opioid blockade study²⁹ revealed that BUP plasma concentrations ≥ 1.25 ng/mL were sufficient for achieving complete opioid blockade.³⁰ Thus, BUP plasma concentrations ≥ 1 ng/mL should, theoretically, be sufficient for suppressing opioid withdrawal and, for the subset of patients who use illicit opioids, BUP plasma concentrations ≥ 1.25 ng/mL should be sufficient to block illicit opioid effects. The results of a recent pharmacokinetic (PK) study indicate that pregnant women treated with BUP-SL may have BUP plasma concentrations < 1 ng/mL, and, thus, be at sub-therapeutic doses, for most of their dosing interval.³¹ Utilizing higher BUP-SL doses²⁶ and more frequent dosing in pregnant women³¹ have been recommended as potential solutions. However, higher doses may be problematic from the perspective of fetus-infant outcomes in that higher maternal BUP-SL doses may be associated with: 1) greater depression of fetal heart rate even at trough;²⁴ 2) lower birth weight and length;³² and 3) greater NAS/NOWS severity.^{32, 33} Using a more frequent dosing schedule may also be problematic in that greater than once daily dosing is associated with lower rates of medication adherence.^{34, 35}

4.1.4 Potential Benefits of Extended Release (XR) formulations

Extended release (XR) formulations can address some of the disadvantages of BUP-SL including potential peak-trough issues, non-adherence^{36, 37} and diversion.³⁶ Two new BUP-XR products (CAM2038 from Braeburn Pharmaceuticals and Sublocade™ from Indivior) have recently been reviewed by the FDA. Once approved, CAM2038 will be marketed as Brixadi; therefore, all instances of CAM2038 in this document also refer to Brixadi. Both products are subcutaneously injected and form a gel deposit under the skin that releases BUP at a steady rate for up to one month; the CAM2038 product is also available as a weekly formulation. The benefits of eliminating potential diversion go beyond the individual patient in that potential diversion is a barrier to prescribing for some BUP-waivered providers;³⁸ removal of this barrier thus has the potential to increase the availability of treatment. This is especially important for pregnant women with OUD for whom there is a sizeable treatment gap.³⁹⁻⁴¹ XR formulations also avert the daily peak-trough cycle of BUP-SL, which, as noted above, is particularly problematic in pregnant women. A BUP formulation that minimizes peak concentrations while also helping to ensure that trough levels are ≥ 1 ng/mL would be ideal for meeting the needs of both the mother and infant; PK data suggest that CAM2038 achieves this. Specifically, the 24 mg weekly CAM2038 formulation approximates 12-16 mg of daily BUP-SL (i.e., the typical target dose range for treating OUD in pregnant women¹³) while having both lower peak (4.97 ng/mL vs. 6.09 ng/mL) and higher trough (1.18 ng/mL vs. 0.85 ng/mL) levels.⁴²

4.1.5 Overview of Protocol Objectives

The present study is a pragmatic multi-site, randomized controlled trial (RCT) with the primary objective of evaluating the impact of treating OUD in pregnant women with BUP-XR, relative to BUP-SL, on mother-infant outcomes. In addition to being the first trial to evaluate BUP-XR in pregnant women, it will be one of the few multi-site RCTs of opioid maintenance treatment conducted with a relatively large sample size of pregnant women. Indeed, only one such RCT has been conducted: the Maternal Opioid Treatment: Human Experimental Research (MOTHER) trial,⁴³ which included 175 participants. The MOTHER trial, which compared methadone and BUP-SL maintenance treatments, was a very important clinical trial with a number of strengths. However, as noted by the investigators, MOTHER was a tightly controlled efficacy study that maximized internal validity at the expense of external validity,⁴⁴ which limits the generalizability of the results to clinical practice. Given the dearth of evidence upon which to base clinical guidance documents,¹³ the present trial is designed to protect internal validity through the use of randomization but to otherwise favor external validity. As noted by Ford and Norrie,⁴⁵ pragmatic

trials are typically not pragmatic on all dimensions. CTN-0080 follows the suggestion to utilize pragmatic features where feasible while still maintaining trial quality and the ability to answer the question of interest.⁴⁵ The rationales for key design decisions related to the primary objective are provided below. A secondary objective of MOMs is to contribute to the science of OUD treatment in pregnant women by testing conceptual models of the mechanisms by which BUP-XR may improve mother and infant outcomes relative to BUP-SL. The conceptual models are described in **section 4.4**. A tertiary objective of MOMs is to conduct a health economic analysis comparing the costs and benefits of BUP-XR and BUP-SL; the rationale for which is described in **section 4.5**. A quaternary objective is to evaluate the impact of BUP-XR, relative to BUP-SL, on infant neurodevelopment; the rationale for which is described in **section 4.6**.

4.2 Rationale for Study Medications

4.2.1 CAM2038 vs. Sublocade™

Two BUP-XR products have been developed recently (CAM2038 from Braeburn Pharmaceuticals and Sublocade™ from Indivior), both of which are subcutaneously injected and form a gel deposit under the skin that releases BUP at a steady rate for up to one month; the CAM2038 product is also available as a weekly formulation. Sublocade™ received FDA approval in 2017. In 2018, the FDA determined that CAM2038 met all safety and efficacy standards necessary for approval but did not approve it for marketing due to exclusivity issues. The monthly formulations of both Sublocade™ and CAM2038 use N-methyl-2-pyrrolidone (NMP), a compound which animal studies suggest may have adverse fetal-infant effects, as an excipient.

The weekly CAM2038 product does not include NMP and, thus, was selected as the BUP-XR medication for MOMs. Specifically, the weekly CAM2038 product will be utilized while participants are pregnant or breastfeeding and the monthly formulation will be utilized during the postpartum phase for women who are not breastfeeding. The weekly CAM2038 product includes three excipients: 1) phosphatidylcholine; 2) glycerol dioleate (GDO); and 3) ethanol. The target weekly CAM2038 dose is 24 mg, but a minority of participants may require the highest dose (32 mg). The maximum potential exposure to the excipients for any participant/fetus would be for a pregnant woman randomizing into MOMs at 6 weeks EGA, delivering at 40 weeks, and receiving the maximum potential CAM2038 dose (32 mg of buprenorphine in 0.64 mL) every week. The maximum potential exposure to these excipients for any participant/breastfeeding infant postpartum would be for a participant receiving the 32 mg CAM2038 dose every week.

Phosphatidylcholine may offer health benefits during pregnancy⁴⁶ and choline supplements of 450 mg/day during pregnancy have been recommended by the Institute of Medicine⁴⁷ and the American Medical Association.⁴⁸ The maximum weekly dose of CAM2038 (32 mg) includes 0.26 grams of phosphatidylcholine; the total possible maximum exposure during pregnancy would be 8.84 grams, which is less than the 107.1 grams that would be consumed by taking the recommended supplement of 450 mg/day. The total maximum exposure postpartum would be 13.52 grams compared to 163.8 grams if the 450 mg/day supplement were continued through one year postpartum. The second excipient, GDO, is a diglyceride and naturally occurs in human plasma. Diacylglycerol, of which GDO is a significant component, is widely used in food products (e.g., mayonnaise, salad dressings, margarine, icing, etc.).⁴⁹ The maximum weekly dose of CAM2038 (32 mg) includes 0.26 grams of GDO; the total possible maximum exposure during pregnancy would be 8.84 grams, which equates to less than one tablespoon (i.e., the total would be 0.69 tablespoons). The total maximum exposure postpartum would be 13.52 grams, which equates to approximately one tablespoon (i.e., the total would be 1.06 tablespoons). The third excipient, ethanol, when consumed in sufficient quantities by pregnant women can have a teratogenic effect.⁵⁰ The maximum weekly dose of CAM2038 (32 mg) contains .061 grams of

ethanol; a standard alcoholic drink in the US contains 14 grams of ethanol.⁵¹ The total maximum exposure to ethanol during pregnancy would be 2.074 grams (i.e., <15% of the ethanol in a single standard drink). Although no level of alcohol exposure is considered safe during pregnancy, the potential substantial benefit of extended-release buprenorphine, relative to sublingual buprenorphine, (e.g., superior PK profile, elimination of diversion potential, improved adherence) justifies any theoretical risk from this negligible amount of subcutaneously injected ethanol. While alcohol use is not encouraged in breastfeeding women, the CDC notes that moderate alcohol use (up to 1 standard drink per day) is not known to be harmful to the infant.⁵² The maximum potential total postpartum exposure (i.e., assuming 52 weeks at the maximum weekly CAM2038 dose) would be 3.172 grams, which is <23% of the ethanol in a single standard drink; thus the risk-benefit ratio for postpartum use is also justified.

4.2.2 BUP-SL vs. Methadone as the Comparator

BUP-SL, as opposed to methadone, was selected as the comparator for MOMs to maximize the potential impact of the study findings on clinical practice. Methadone can only be dispensed by licensed opioid treatment programs, which are highly regulated and have relatively limited availability. BUP, by contrast, is more widely available since it can be prescribed in office-based practices by certified practitioners. For outpatient practitioners, the results of a trial comparing a medication they can prescribe for the treatment of OUD (BUP-XR) to one they cannot prescribe (methadone) is likely to have little impact on practice. By using BUP-SL as the comparator, MOMs has the potential to show that BUP-XR is not inferior, and perhaps superior, to BUP-SL and, thus, is a reasonable alternative to BUP-SL, thus expanding the available treatment options.

4.2.3 BUP-SL and BUP/NX-SL

Participants randomized to BUP-SL will receive buprenorphine, without (BUP-SL) or with naloxone (BUP/NX-SL). The primary rationale for allowing both medications is to avoid discouraging site/patient participation by requiring the use of a medication that is inconsistent with site preference. In addition, allowing both medications is consistent with the goal of maintaining a pragmatic design where feasible. The inclusion of both BUP-SL and BUP/NX-SL may also make a valuable contribution to the field. As noted by Nguyen and colleagues,⁵³ BUP-SL is more commonly used in pregnant women based on the principal of limiting fetal exposure to additional compounds and the potential for induced withdrawal if BUP/NX-SL is injected, but BUP-SL is more likely to be diverted and misused than BUP/NX-SL. The existing literature on the relative safety of utilizing BUP/NX-SL during pregnancy is limited to retrospective chart reviews,⁵³ which generally have found no evidence of worse outcomes with BUP/NX-SL^{54, 55} with the exception of a recent study which found rates for prematurity and low birth weight that were higher than expected.⁵³ In addition to being retrospective, the study sample sizes have been limited (i.e., N=10,⁵⁶ N=30,⁵⁷ N=7,⁵⁴ N=26,⁵³ N=31⁵⁸). It is anticipated that at least three of the approximately 10 sites will utilize BUP/NX-SL; hence, it is estimated that a minimum of 38 MOMs participants will be taking BUP/NX-SL. Exploratory analyses of safety information comparing participants taking BUP-SL to those taking BUP/NX-SL could make an important contribution to the field.

4.3 Rationale for Clinical Trial Design Elements

4.3.1 Open-Label vs. Double Dummy Design

As noted above, there is a dearth of evidence on which to base clinical guidance documents for the treatment of OUD in pregnant women.¹³ Consistent with the CTN mission, this trial is designed to compare the effectiveness of interventions as they would be used in the real world. The present trial is, thus, designed to protect internal validity using randomization but to otherwise favor

external validity. In addition to not representing clinical practice, the use of a double dummy design would artificially remove a key advantage of BUP-XR: avoiding daily self-administration; hence, MOMs is an open-label trial.

4.3.2 Medication Check Visits vs. Research Visits

In a pragmatic trial, research assessments/interactions that could impact outcomes and, thus, reduce the generalizability of the results to real world practice are minimized. However, this goal must be balanced with the need to closely monitor safety given that CTN-0080 is the first trial to evaluate the BUP-XR formulation in pregnant women. This balance will be achieved by including weekly Medication Check Visits, which include a minimal number of assessments and procedures (see **Table 3**), while limiting more intensive data collection to Research Visits, which will occur less frequently (e.g., monthly during pregnancy, etc.; see **Table 3**).

4.3.3 Non-inferiority Primary Analysis

As detailed in the conceptual model (**section 4.4**), BUP-XR may improve outcomes, relative to BUP-SL, due to its superior PK profile. However, to be consistent with the design of the CAM2038 Phase 3 trial,⁵⁹ CTN-0080 will utilize a non-inferiority design. A finding of non-inferiority would suggest that BUP-XR is a reasonable alternative to BUP-SL, thus expanding available treatment options. This is important because, at present, the number of BUP providers is insufficient to meet treatment needs (particularly in rural areas). A significant concern of clinicians who are unwilling to prescribe BUP-SL is the potential for diversion;³⁸ removal of this barrier would, thus, have the potential to increase the availability of treatment.

4.3.4 Standardization of NOWS Scoring and Treatment

The primary outcome measure for CTN-0080 is illicit opioid use during pregnancy. This, combined with the goal of utilizing pragmatic features where feasible, suggests that standardization of NOWS scoring/treatment at the delivery hospitals, which are not participating in the trial as study sites, should not be undertaken. However, the variability in delivery-hospital approach to NOWS could adversely impact the evaluation of treatment effects on NOWS severity, which is a key secondary measure. Hence, it was decided to decrease delivery-hospital variability. Based on a review of the literature, as well as consensus of the NOWS experts of the protocol development team, it was determined that participants are only eligible (see **section 6.4.2**) if they plan to deliver at a hospital that meets all the following requirements:

- 1) has a written protocol for the management of NAS/NOWS since it has been shown that implementation of a standard protocol decreases length of opioid treatment days, infant LOS, and use of adjunctive drug therapy.^{60, 61} Based on a survey of Better Outcomes Through Research for Newborns (BORN) hospitals,⁶² it is estimated that 88% of potential delivery hospitals will have a written protocol for NAS/NOWS management.
- 2) offers rooming-in while infants are being observed for NAS/NOWS, since rooming-in is associated with decreased need for pharmacologic treatment for NAS/NOWS and shorter LOS.⁶³ Based on the results of the BORN survey,⁶² it is estimated that 73% of potential delivery hospitals will offer rooming-in.
- 3) does not send infants home on opioids for the treatment of NAS/NOWS. This is required since infant NOWS severity will be measured by total number of opioid treatment days as assessed by medical record; opioids provided at home would not be captured making the outcome inaccurate. Based on the results of the BORN survey,⁶² it is estimated that 83% of potential delivery hospitals will not send infants home on opioids.

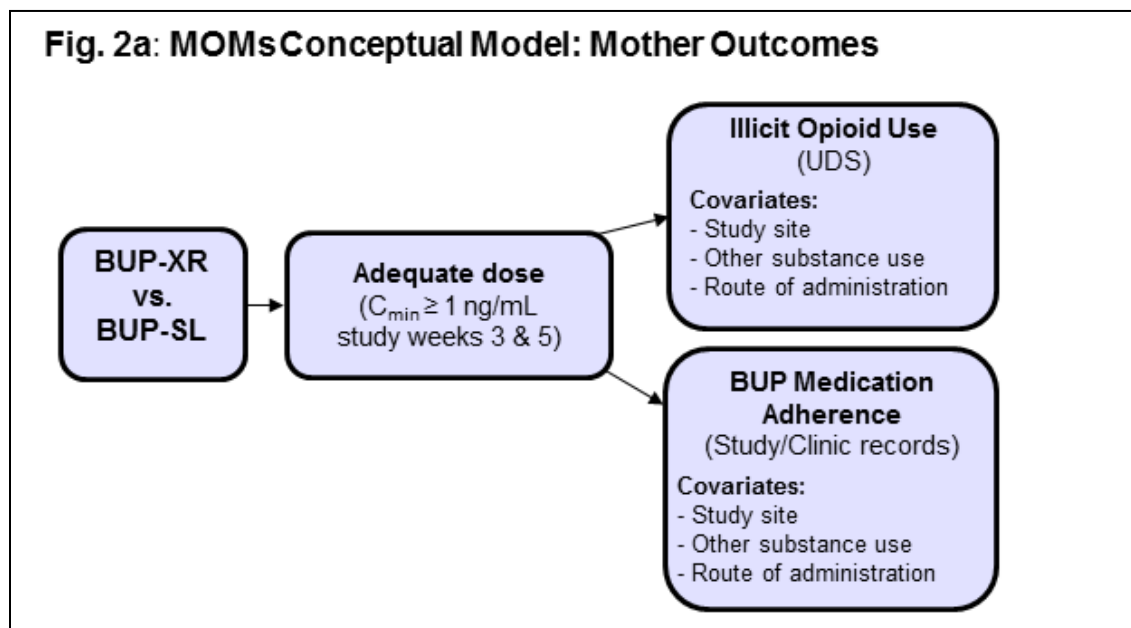

In addition, participants are only eligible to participate (see **section 6.4.2**) if they plan to deliver at a hospital that has provided information about their approach to NAS/NOWS, so that important variables can be controlled for in the NOWS analyses (see **section 7.4.2**).

4.3.5 Potential Ancillary Studies

CTN-0080 has the potential to serve as a parent trial for ancillary studies that could make further important contributions to the field. It is likely that ancillary studies will be conducted at a subset of sites due to the need 1) for specific expertise and/or equipment that may not be available at all locations and 2) to avoid overwhelming potential CTN-0080 participants with study requests. An example of the former would be a study of brain development requiring pediatric neuroimaging. Another example of an ancillary study, the pursuit of which will be encouraged by interested investigators, would be a lactation sub-study to assess the exposure of the infants to buprenorphine and/or buprenorphine-naloxone through breastfeeding. There are a limited number of lactation studies with women maintained on BUP-SL,⁶⁴⁻⁶⁷ with the largest study including 10 women.⁶⁷ To date, there are no published lactation studies for breastfeeding women maintained on BUP/NX-SL. Thus, even a relatively small lactation sub-study could contribute valuable information to the field.

4.4 Conceptual Model

A secondary objective of MOMs is to test a conceptual model of the mechanisms by which BUP-XR may improve mother and infant outcomes relative to BUP-SL; the conceptual models to be tested are outlined in **Figures 2a** (mother outcomes) and **2b** (infant outcomes).

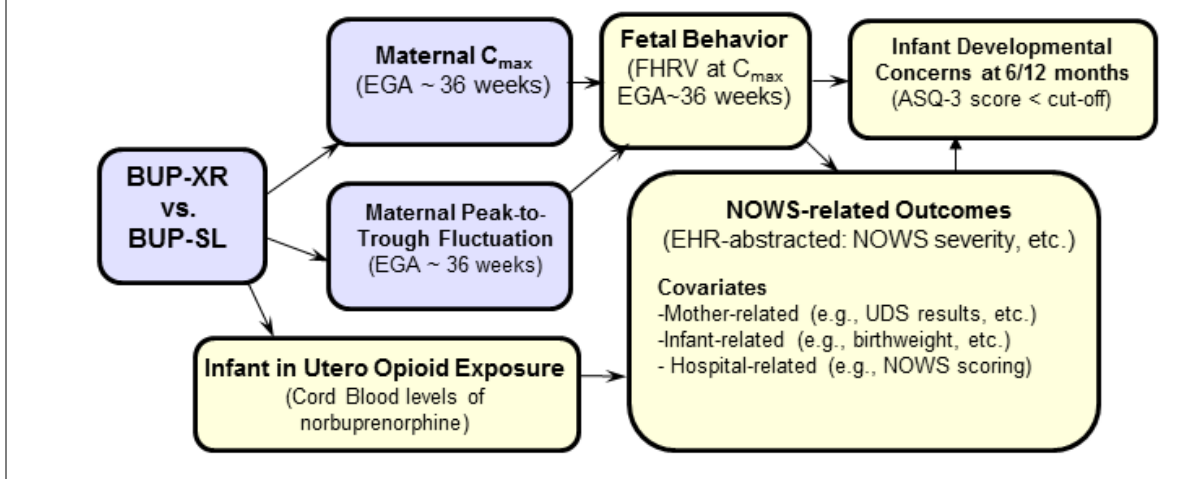

4.4.1 Mother Outcomes

The conceptual model describing the mechanism by which BUP-XR may improve mother outcomes relative to BUP-SL is outlined in **Figure 2a**. As noted above, BUP plasma concentrations ≥ 1 ng/mL should be sufficient for suppressing opioid withdrawal²⁷ and, for the subset of participants using illicit opioids, BUP plasma concentrations ≥ 1.25 ng/mL should be sufficient to block the illicit opioid effect.³⁰ The main conceptual model will focus on the ≥ 1 ng/mL threshold since this should apply to all of the participants whereas the ≥ 1.25 ng/mL threshold is

pertinent for participants using illicit opioids; the ≥ 1.25 ng/mL threshold will be evaluated in exploratory analyses. There is evidence that pregnant women may have BUP plasma concentrations < 1 ng/mL for most of their dosing interval.³¹ It has been hypothesized that inadequate BUP plasma concentrations may account for illicit opioid use and treatment dropout in pregnant women treated with BUP-SL.²⁶ For participants who consent to the CMA sub-study, trough BUP plasma levels (C_{\min}) will be assessed in conjunction with the study week 3 and 5 visits. Based on the half-life of BUP-XR,²⁹ it is estimated that steady state will be reached at approximately study days 20-25; thus, steady state should be reached by study week 5. The rationale for including the week 3 sample is that, in order to predict treatment dropout, data need to be obtained from participants who subsequently dropout and research suggests that BUP dropout tends to occur within the first 30 days of treatment.^{2, 16} Based on its PK profile, BUP-XR, relative to daily BUP-SL, should result in a greater proportion of women with $C_{\min} \geq 1$ ng/mL, which, in turn, is hypothesized to result in less illicit opioid use and better BUP medication adherence. However, the difference in C_{\min} between the BUP-XR and BUP-SL groups should be less pronounced in women following a split dosing schedule (i.e., taking BUP-SL more than once a day) or a higher dose; thus, BUP-SL dosing frequency and dose will be used to define BUP-SL subgroups. Three covariates that are likely to impact mother outcomes will be controlled for in the analyses: 1) study site (e.g., due to the provision of different psychosocial services, etc.); 2) use of other substances; and 3) route of administration of illicit opioid use (intravenous vs. not intravenous). It is important to note that C_{\min} is being measured to test a conceptual model; there is insufficient evidence to support its use in guiding BUP dosing decisions and the results will not be given to the treating provider.

4.4.2 Infant Outcomes

The conceptual model describing the mechanisms by which BUP-XR may improve infant outcomes relative to BUP-SL is provided in **Figure 2b**. In this conceptual model, fetal behavior, as measured by fetal heart rate variability (FHRV)^{68, 69} at maternal BUP C_{\max} at ~36 weeks EGA, is hypothesized to be directly related to both infant development and NOWS-related outcomes. Fetal exposure, as indicated by cord norbuprenorphine plasma levels, is hypothesized to be related to NOWS-related outcomes and NOWS-related outcomes are hypothesized to be related to infant development.

Fig. 2b: MOMs Conceptual Model: Infant Outcomes

Maternal peak BUP plasma level (C_{\max}) and fetal behavior. BUP C_{\max} is associated with adverse fetal effects, including decreased FHRV.²⁴ PK data suggest that the 24 mg weekly formulation of CAM2038, relative to 16 mg of daily BUP-SL, has a lower C_{\max} (4.97 ng/mL vs. 6.09 ng/mL) level.⁴² It is thus predicted that the BUP-XR group will have lower C_{\max} , relative to the BUP-SL group, and, thus, have greater FHRV. However, the difference should be less pronounced in women following a split dosing schedule or at a lower dose; thus, BUP-SL dosing schedule and dose will be used to define BUP-SL subgroups.

Maternal peak-to-trough fluctuation and fetal behavior. It has been hypothesized that the daily peak-to-trough fluctuation associated with opioid maintenance treatment results in the fetus experiencing withdrawal, which negatively affects fetal health.⁷⁰ It is predicted that the greater the maternal peak-to-trough fluctuation, the greater the level of withdrawal the fetus will experience. PK data suggest that the 24 mg weekly formulation of CAM2038, relative to 16 mg of daily BUP-SL, has both lower C_{\max} (4.97 ng/mL vs. 6.09 ng/mL) and higher C_{\min} (1.18 ng/mL vs. 0.85 ng/mL) levels.⁴² It is, thus, predicted that the BUP-XR group will have a smaller peak-to-trough fluctuation, relative to the BUP-SL group, and, thus, have greater FHRV. However, the difference should be less pronounced in women following a split dosing schedule or at a lower dose; thus, BUP-SL dosing schedule and dose will be used to define BUP-SL subgroups.

Infant Development. Recent reviews have noted the need to consider the longer-term impact of in utero exposure to opioid maintenance on children, for which there is currently a dearth of research.¹⁴ The 6-month and 12-month versions of the Ages and Stages Questionnaire, third edition (ASQ-3)⁷¹ will be used to screen infants for developmental issues. The ASQ-3 is a validated, parent-administered screen used throughout the world⁷¹⁻⁷³ and deemed appropriate for assessing infants exposed to opioids in utero.¹³ An association between FHRV and development has been found in a number of studies.⁷⁴⁻⁷⁶ Furthermore, a recent study found that the relationship between maternal depression and neonatal neurobehavioral immaturity was mediated by FHRV.⁷⁷ It is thus predicted that fetal behavior, as measured by FHRV, will be a significant predictor of scoring below the ASQ-3 cut-off. Research has also found a relationship between NOWS severity and infant development^{78, 79} and it is, thus, predicted that NOWS-related outcomes will predict ASQ-3 scores.

NOWS-related outcomes. Approximately 50% of infants born to women on opioid maintenance treatment will experience NAS/NOWS.¹⁴ Factors that can impact NOWS include maternal polysubstance use,^{32, 80} EGA at delivery and birth weight,^{81, 82} and nonpharmacological treatment approaches.⁸³ Controlling for these factors as needed, the mechanisms by which BUP-XR, relative to BUP-SL, may impact NOWS-related outcomes will be evaluated. It has been hypothesized that the daily peak-to-trough fluctuation associated with opioid maintenance treatment results in the fetus experiencing withdrawal, which increases the incidence and severity of NAS/NOWS.⁷⁰ Consistent with this hypothesis, a retrospective study evaluating NAS/NOWS incidence in infants born to mothers maintained on a split-dosing schedule of methadone reported a lower incidence of NAS/NOWS (29%)⁷⁰ relative to the 50% typically associated with methadone maintenance.^{14, 83} It is thus predicted that fetal behavior, as measured by FHRV, will be a significant predictor of NOWS outcomes.

Infant in utero opioid exposure and NOWS-related outcomes. Another key factor in determining NOWS severity is, of course, infant in utero opioid exposure. Research suggests that exposure to norbuprenorphine, a major active metabolite of BUP, may play an important role in the development of NOWS. EGA at delivery is positively associated with NAS/NOWS severity^{81, 82} and placenta conversion of BUP to norbuprenorphine increases with increasing EGA.⁸⁴ Research has found a significant positive association between infant norbuprenorphine levels and hospital LOS.⁸⁵ In addition, a recent study found a significant positive association between norbuprenorphine levels in cord blood and the need for pharmacotherapy for NAS/NOWS.⁸² While data on placenta conversion of BUP to norbuprenorphine is not available for BUP-XR, PK data suggest that there is less first-pass metabolism of BUP to norbuprenorphine for BUP-XR, with norbuprenorphine:BUP ratios 3-7 times lower for BUP-XR compared to BUP-SL.⁸⁶ Hence, it is predicted that norbuprenorphine levels in infants, as assessed in cord blood, will be significantly lower in the BUP-XR, relative to BUP-SL, group, which will, in turn, be predictive of lower NOWS severity. Assessing buprenorphine and its metabolites in cord blood offers an additional advantage in understanding the relationship between maternal BUP treatment and NOWS. Specifically, genetics likely play a role in infant in utero opioid exposure^{87, 88} but much work remains to fully elucidate the genetic factors involved.^{84, 89} It has been suggested that evaluating BUP and its metabolites in cord blood allows an evaluation of opioid exposure that reflects the end product of maternal, placental, and fetal genetics⁸² and, thus, genetics will be taken into account in this manner.

4.5 Health Economics

NAS/NOWS and OUD are public health priorities. As mentioned above, NAS/NOWS is associated with adverse health effects for the infant⁷⁻⁹ and with costly hospitalizations.⁶ OUD is associated with lower health-related quality of life (HRQoL)⁹⁰; excess high-cost healthcare utilization (e.g., emergency department visits and inpatient admissions)^{91, 92}; and other adverse personal and social consequences that, in total, cost the U.S. over \$500 billion, annually.⁹³ BUP-SL has been shown to be effective and cost-effective in treating OUD, resulting in improved HRQoL and reduced healthcare costs; however, evidence of these effects among pregnant women/new mothers with OUD does not exist.⁹⁴ As also noted above, adherence to OUD pharmacotherapy can be problematic among pregnant women,^{14, 20} an issue that can be addressed with XR formulations;^{36, 37} however, the additional cost of BUP-XR may serve as a barrier to adoption. The wholesale acquisition costs for CAM2038 have not been established. The current wholesale acquisition costs per monthly dose of Sublocade™ is \$1,580, versus \$489 and \$406 for monthly doses of 16mg/day buprenorphine-naloxone film (Suboxone®) and generic tablets, respectively.⁹⁵ Focusing on the cost of the therapy in isolation is shortsighted, as it does not account for the many

potential value offsets associated with effective treatment of OUD; understanding the relative costs/benefits of BUP-XR is thus a tertiary objective of the MOMs trial.

4.6 Infant Neurodevelopment

There have been relatively few well-designed studies of neurodevelopmental outcomes among children prenatally exposed to opioid agonist medications. The reported data have been sparse and often conflicting⁹⁶ and this represents a substantial knowledge gap.¹⁴ A systematic review and meta-analysis from 2014 was able to include only five studies quantitatively reporting neurobehavioral function, and the included studies were all assessed as “weak” or “moderate” quality, with relatively small samples.⁹⁷ Though there were trends for poorer outcomes, the meta-analysis showed no significant impairments for the children exposed to chronic opioids in-utero, compared to the non-exposed children. A recent retrospective chart review suggested deleterious neurodevelopmental effects of chronic in-utero opioid exposure,⁷⁸ but considerable methodological issues with the study design and its interpretation have been noted.⁹⁸ The results from a prospective, longitudinal study of 96 infants from the MOTHER trial suggest that there were no significant adverse neurodevelopmental effects from either prenatal opioid exposure (with no difference between methadone- and buprenorphine-maintenance) or opioid treatment for NAS/NOWS.⁹⁹

In light of the relative dearth of high-quality research data available on this important topic, the MOMs trial presents an opportunity to conduct neurodevelopmental assessments on a relatively large sample of children with prenatal exposure to buprenorphine and to evaluate these data while controlling for a number of prospectively collected contributing factors.^{98, 100} The CTN-0080 parent trial includes the collection of the Ages and Stages Questionnaire, third edition (ASQ-3) at two time points – when the infant is approximately 6 and 12 months of age (see **section 7.2.2.3**). The ASQ-3 is a validated, parent-administered screen used throughout the world⁷¹⁻⁷³ and deemed appropriate for assessing infants exposed to opioids in utero.¹³ In addition, the ASQ-3 can be completed by the caregiver in his/her home and mailed to the research team; this convenience might serve to increase completion rates. However, some research has found relatively poor agreement between the ASQ-3 and the BayleyTM-4, which is considered to be a gold standard assessment of early child development.¹⁰¹

Thus, a quaternary objective of the MOMs trial is to evaluate the impact of BUP-XR, relative to BUP-SL, on infant neurodevelopment as measured by the BayleyTM-4 when the infant/child is approximately 12 and 24 months of age (see **section 8.10**).

5.0 STUDY OBJECTIVES

5.1 Primary Objective

The primary objective of this trial is to evaluate the impact of treating OUD in pregnant women with BUP-XR, compared to BUP-SL, on mother and infant outcomes. It is hypothesized that the BUP-XR, relative to the BUP-SL, group will:

- 1) not have greater illicit opioid use during pregnancy (primary, non-inferiority);
- 2) have lower infant neonatal opioid withdrawal syndrome (NOWS) severity (key secondary, superiority); and
- 3) not have greater postpartum illicit opioid use (key secondary, non-inferiority).

5.2 Secondary Objective

Testing a conceptual model of the mechanisms by which BUP-XR may improve mother-infant outcomes, relative to BUP-SL, is a secondary trial objective.

5.3 Tertiary Objective

To determine the economic value of BUP-XR, compared to BUP-SL, in the treatment of OUD among pregnant mothers by evaluating the cost of each treatment strategy, changes in the utilization of associated treatment and other healthcare services, and improvements in health-related quality-of-life (HRQoL), measured as quality-adjusted life-years (QALYs), is a tertiary trial objective. We anticipate that a larger reduction in the utilization of high-cost healthcare services and increase in QALYs will result in BUP-XR being cost-effective compared to BUP-SL from a healthcare sector perspective, according to traditionally accepted value thresholds.

5.4 Quaternary Objective

The quaternary objective is to evaluate the impact of BUP-XR, relative to BUP-SL, on neurodevelopment when the infant/child is approximately 12 and 24 months of age. The main outcome of interest is the score on the cognitive subscale of the BayleyTM-4¹⁰² at the 24-month assessment. Based on the outcomes of the MOTHER neurodevelopmental study,⁹⁹ it is predicted that prenatal buprenorphine exposure will not result in significant adverse neurodevelopmental outcomes and that there will be no difference between the BUP-XR and BUP-SL treatment arms.

6.0 STUDY DESIGN

6.1 Overview of Study Design

This is an intent-to-treat, two-arm, open-label, pragmatic RCT. Eligible participants will be randomized in a 1:1 ratio to BUP-XR or BUP-SL, balancing on site, EGA at time of randomization (6 weeks – 18 weeks vs. 19 weeks – 30 weeks), and whether they are on BUP-SL at the time of randomization (yes vs. no). Participants will be provided BUP-XR/BUP-SL through 12 months postpartum. Key outcome measures are: 1) the proportion of illicit opioid-negative urines during pregnancy (primary); 2) infant's NOWS severity, as assessed by total days of opioid treatment derived from the infant's medical record (key secondary); and 3) proportion of illicit opioid-negative urines during the 12-month postpartum phase (key secondary). Safety measures will include adverse events, mood measures, and delivery-related outcomes.

6.2 Number of Sites and Participants

Approximately 200 participants, recruited from approximately 10 sites, will be randomized into the trial. Pregnant patients who have an EGA of 6 - 30 weeks at randomization, and, in the judgment of the treating provider, are good candidates for BUP-maintenance treatment will be recruited for the study. Participants may be recruited from a variety of other sources, including advertising, but must have completed intake at a study site to be eligible for randomization. Recruitment advertisements will be approved by the Institutional Review Board (IRB). Efforts will be made to recruit a study sample that reflects, or exceeds, the proportion of minorities in treatment at the sites.

6.3 Study Duration

Sites will be initiated on a rolling basis. Once all sites are initiated, enrollment is expected to take place over a period of approximately 32 months. Duration of participation may vary from approximately 15 months to 22 months (e.g., depending on the time taken to complete screening/baseline, EGA at enrollment, etc.) for the main CTN-0080 trial.

6.4 Site and Participant Selection

6.4.1 Site Selection

A pragmatic trial should include a mix of sites/investigators that are representative of real world practice and that possess the skills to effectively implement the study intervention.⁴⁵ To this end, CTN-0080 seeks to include a mix of academically-affiliated and community clinics. Evaluating BUP-XR, compared to BUP-SL, in the treatment of pregnant women with OUD under real world conditions requires that sites already have experience with BUP-SL dosing in pregnant women. The majority of the site eligibility criteria outlined in **section 6.4.1.1** are the minimum requirements needed to successfully implement MOMs. The criterion related to delivery hospitals is included to reduce variability in neonatal outcomes and to ensure that important covariates can be collected and accounted for in the data analyses. The recommended model of care for pregnant women with OUD is one in which there is close collaboration between prenatal care and addiction treatment providers and, where possible, integrated treatment.¹³ This approach will be used by all sites eligible for CTN-0080, but the treatment components will likely vary among sites. A review of the literature failed to identify an instrument for characterizing models of care for the management of pregnant women with OUD; such an assessment will be developed and used to characterize treatment at the MOMs sites (see **section 7.4**).

6.4.1.1 *Site Characteristics*

Participating sites should:

1. provide BUP to pregnant women in an “office-based” setting (i.e., outside of a treatment program requiring daily/near-daily in-clinic administration);
2. offer OUD treatment (including BUP) for patients following delivery for ≥ 12 months;
3. include a close collaboration between prenatal care and addiction treatment providers;
4. be willing to comply with study procedures, including weekly Medication Check Visits with participants;
5. enroll enough potentially eligible patients to meet the target randomization of 1.25 per month;
6. have access to a medical clinician who can prescribe BUP (the degree and licensing requirements depend on the regulations of the state in which the site is located), to determine participant eligibility, and to regulate the medication dose appropriately;
7. have access to, or the ability to contract with, a pharmacy/pharmacist (or other appropriately qualified entity based on local/state regulations) to store/dispense study medications;
8. be able to provide after-hours clinical back-up for study-related emergencies;
9. have access to, or the ability to contract with, a phlebotomist or other appropriate professional, to complete blood draws;
10. have $\geq 75\%$ of their pregnant patients delivering at hospitals that: a) have a written protocol for the management of NAS/NOWS; b) offer rooming-in while infants are being observed for NAS; c) do not send infants home on opioids for the treatment of NAS/NOWS; d) have agreed to complete the BORN survey (see **section 7.4.2**) at two time-points (e.g., pre-site initiation and post-delivery for the final site participant).

6.4.2 Participant Selection

The eligibility criteria for a pragmatic trial should define participants representative of the patient pool for whom the intervention would be utilized.⁴⁵ The rationale for each eligibility criterion is provided in **section 6.4.2.3**.

6.4.2.1 *Inclusion Criteria*

Potential participants must:

1. be 18-41 years of age;
2. be pregnant with an EGA of 6 - 30 weeks at randomization, have evidence of a viable intrauterine pregnancy (IUP) if EGA < 12 weeks, and is not planning to terminate the pregnancy;
3. have a single fetus pregnancy (can be based on self-report if an objective assessment is unavailable);
4. meet DSM-5 criteria for moderate/severe OUD and be a good candidate for BUP maintenance and/or be currently prescribed BUP for the treatment of OUD;
5. be willing to be randomized to BUP-XR or BUP-SL and to comply with study procedures, including weekly Medication Check Visits;

6. be planning to deliver at one of the hospitals for which the BORN survey was completed and that: a) has a written protocol for the management of NAS/NOWS, b) offers rooming-in while infants are being observed for NAS/NOWS; and c) does not send infants home on opioids for the treatment of NAS/NOWS;
7. be enrolled in outpatient addiction treatment at a participating site (e.g., have completed intake);
8. be able to understand the study, and having understood, provide written informed consent in English.

6.4.2.2 *Exclusion Criteria*

Potential participants must not:

1. have a physiological dependence on alcohol or sedatives requiring medical detoxification;
2. have a psychiatric condition that, in the judgment of the site medical clinician (MC), would make study participation unsafe or which would make treatment compliance difficult;

Examples include:

- Suicidal or homicidal ideation requiring immediate attention
 - Severe, inadequately-treated mental health disorder (e.g., active psychosis, uncontrolled bipolar disorder)
3. have a medical condition that, in the judgment of the site MC, would make study participation unsafe or which would make treatment compliance difficult. Medical conditions that may compromise participant safety or study conduct include, but are not limited to, allergy/sensitivity to study medications and the following based on clinical labs:
 - AST/ALT greater than 5X upper limit of normal
 - serum creatinine greater than 1.5X upper limit of normal
 - total bilirubin greater than 1.5X upper limit of normal
 4. be currently in jail, prison, or any inpatient overnight facility as required by court of law or have pending legal action or other situation (e.g., unstable living arrangements) that, in the judgement of the site investigator, could prevent participation in the study or in any study activities;
 5. be currently receiving methadone or naltrexone treatment;
 6. be enrolled in or planning to enroll in treatment beyond the level 3.3 (Clinically Managed Population-Specific High-Intensity Residential Services) of the American Society of Addiction Medicine criteria; for level 3.3, the participant must have the ability to leave the facility unaccompanied by staff as needed;¹⁰³
 7. be enrolled in or planning to enroll in: a) a trial testing medication for managing OUD during pregnancy; b) research testing an intervention for substance use disorder or NOWS in their infant unless they are willing to provide a release for the research records.

6.4.2.3 Rationale for Eligibility Criteria

The rationale for each inclusion and exclusion criterion is provided in **Table 1**. Some criteria were selected to reflect the eligibility criteria from the MOTHER study⁴³ in order to increase the comparability of the MOTHER and MOMs study samples.

Table 1: Rationale for Study Eligibility Criteria

Criterion#	Criterion Description	Criterion Rationale
I1	18-41 years of age	Definition of Study Sample (adults); >41 year of age associated with obstetrical problems; MOTHER eligibility criterion
I2	Pregnant, 6-30 weeks EGA; evidence of viable IUP if EGA <12 weeks; not planning to terminate	Definition of Study Sample (pregnant); MOTHER eligibility criterion
I3	Single fetus pregnancy	Multiple fetuses associated with poorer neonatal outcomes; MOTHER eligibility criterion
I4	DSM-5 criteria for OUD, BUP candidate; prescribed BUP	Definition of Study Sample (candidates for BUP-maintenance treatment)
I5	Willing to be randomized; comply with study procedures	To help ensure that the participant will provide useful data
I6	Delivery hospital criteria	NOWS approach standardization
I7	Completed intake for treatment at study site	Required by study design (evaluating medication within Substance Use Disorder [SUD] treatment context)
I8	Understand study/give consent	Good Clinical Practice (GCP) Requirement
E1	Alcohol/sedative physiological dependence	Safety
E2	Psychiatric condition making participation unsafe/difficult	Safety and to help ensure that the participant will provide useful data
E3	Medical condition making participation unsafe/difficult	Safety and to help ensure that the participant will provide useful data
E4	Situation that could prevent participation in the study/study activities	To help ensure that the participant will provide useful data
E5	Taking methadone/naltrexone	Contraindication
E6	Beyond 3.1 treatment level	To reduce sample heterogeneity
E7	Other research participation	Would adversely impact study validity (a) or may add variance that needs to be accounted for (b)

7.0 STUDY MEASURES

Ideally, pragmatic trial measures would be obtained unobtrusively in order to reduce participant burden and to avoid research assessments/interactions that could impact outcomes and, thus, reduce the generalizability of the results to real world practice; however, some outcomes can only be obtained with participant input.⁴⁵ CTN-0080 is designed to rely, as much as possible, on medical record data and to collect data directly from participants only when measures reflect important outcomes or are needed to interpret outcomes (i.e., explanatory variables).

7.1 Key Outcome Measures of the Primary Objective

7.1.1 Primary Outcome - Illicit Opioid Abstinence During Pregnancy

Avoiding illicit opioid use is a key rationale for providing opioid maintenance therapy to pregnant women with OUD. While BUP-SL is effective in reducing illicit opioid use, the CAM2038 Phase 3 trial revealed that CAM2038 was superior to BUP/NX-SL on the proportion of illicit opioid-negative urine samples.¹⁰⁴ MOMs will use proportion of illicit opioid-negative urine samples during pregnancy as the primary outcome.

Urine samples will be collected at the time of the weekly Medication Check Visits, ideally using temperature monitoring, and the validity of urine samples will be checked with the use of a commercially available adulterant test. In cases where the temperature reading (when available) or adulterant test indicates a non-valid sample, an attempt will be made to obtain a second urine sample. Samples will be shipped to a central lab for analysis using a rapid UDS system. Urine samples will be tested for: buprenorphine/ norbuprenorphine, fentanyl, cocaine, methamphetamine, amphetamine, opioids, marijuana, benzodiazepines, methylenedioxymethamphetamine (MDMA, Ecstasy), barbiturates, methadone, oxycodone, phencyclidine (PCP), cotinine, and ethyl glucuronide, which is a biomarker of alcohol consumption. The UDS results will not be provided to the study site staff. The UDS system to be utilized has a 0% false positive rate as determined by comparing the results of reported accuracy test samples^{105, 106} with standard GC/MS cut-offs for each substance.^{107, 108} However, as noted by SAMHSA¹³ and ACOG,¹⁰⁹ there is a possibility for false positives with any qualitative test (due to cross-reactions, etc.); hence, *in a clinical scenario*, a positive result *should be subjected to confirmatory testing*, given its potential ramifications (e.g., potential reporting requirements). Given the low false positive rate of the UDS system being utilized and the fact that research results will not be utilized for clinical decisions, we feel confident that confirmatory testing is not necessary. For primary outcome scoring, missing urine samples will be imputed as positive for illicit opioids, which is consistent with the approach taken in the CAM2038 Phase 3 trial¹⁰⁴ and with the greater likelihood of illicit opioid use in patients not engaged in treatment.^{110, 111} The number of UDSs expected for each participant will differ based on the length of the pregnancy, thus the number of UDSs potentially imputed will also differ for each participant.

7.1.2 Key Secondary Outcomes (Primary Objective)

7.1.2.1 NOWS Severity

NOWS severity will be assessed by total days of opioid treatment during the hospital stay, which is a definition that has been used in past research.⁶⁰ This outcome will be abstracted from the medical record.

7.1.2.2 *Postpartum Illicit Opioid Abstinence*

Illicit opioid abstinence postpartum will be assessed in a similar fashion to illicit opioid abstinence during pregnancy (see **section 7.1.1**).

7.2 **Secondary Outcome Measures (Primary Objective)**

7.2.1 **Mother Secondary Outcomes**

7.2.1.1 *BUP Medication Adherence*

Adherence to BUP treatment during pregnancy through 12 months postpartum is a clinically important outcome due to the heightened vulnerability to relapse¹³ and overdose²² during this period. Adherence to BUP treatment during pregnancy will be scored as the number of days of adherence divided by the number of days between randomization and delivery. Postpartum adherence to BUP treatment will be scored as the number of days of adherence post-hospital-discharge divided by the number of post-hospital-discharge days in the 12-month postpartum phase. Adherence to BUP-XR will be based on study records (i.e., BUP-XR Injection documentation). For BUP-XR, the receipt of a weekly injection will be scored as 7 days of adherence. If a particular day is covered by two injection windows (e.g., injections on study day 7 and study day 13, where study day 6 overlaps the two seven-day windows), the adherent day will only be counted once. For monthly injections, a participant will be considered as adherent for 28 days and overlapping intervals are handled similarly as for the weekly injections. Adherence to BUP-SL will be defined as: 1) study records showing that BUP-SL was dispensed to the participant (i.e., BUP-SL Dispensing documentation); 2) self-reported adherence will be assessed at the weekly Medication Check Visits; and 3) UDSs positive for buprenorphine/norbuprenorphine. In cases where participants discontinue study medication to transfer to an alternative treatment (e.g., methadone, extended-release naltrexone), a score of 0 days of adherence will be given for the time period post discontinuation. The rationale for not “crediting” receipt of methadone or extended-release naltrexone as adherence is that a switch to an alternative medication is an indicator that BUP-XR / BUP-SL was, in some way, ineffective for the participant and the score of 0 is consistent with the lack of effectiveness. In cases where participants discontinue study medication to transfer to BUP from an alternative provider or were provided non-study BUP during hospital stays or incarceration, a release of information will be obtained, and adherence will be based on clinic/pharmacy records (BUP-XR) or, for BUP-SL, on clinic/pharmacy records along with participant self-report and study UDSs if available. For the case where clinic/pharmacy records could not be obtained for any reason, the participant will be considered non-adherent. If participants drop out of the study prematurely, they will be considered non-adherent for all days after drop-out. In the case of intermittent missing UDSs (e.g., UDSs not collected for any reason but the participant did not drop out), then adherence will be based on study/clinic/pharmacy records and self-report.

7.2.1.2 *Drug and Alcohol Abstinence*

Drug and alcohol abstinence during pregnancy and postpartum are secondary outcomes and will be assessed in a fashion similar to the assessment of illicit opioid abstinence, but rather than being restricted to illicit opioid use, will include alcohol and other drugs of abuse. Missing urine samples will be imputed as positive.

7.2.1.3 *The Opioid Craving Scale*

Craving will be assessed with the Opioid Craving Scale, which was utilized in CTN-0030 and shown to have predictive validity.¹¹² The total score is calculated by averaging the scores from three visual analogue scales which assess craving, cue-induced craving, and likelihood of using.

7.2.1.4 *Adequacy of Prenatal Care Utilization*

Kotelchuck's Adequacy of Prenatal Care Utilization (APNCU) index,¹¹³ which is a well-established index,¹¹⁴ will be used to assess the adequacy of prenatal care. The APNCU includes two indices that are combined to obtain a total score. One index is the timing of prenatal care initiation scored in 4 categories [EGA months: 1) 1 and 2; 2) 3 and 4; 3) 5 and 6; and 4) 7 to 9]. The second is the ratio of observed to expected visits based on the length of time between the first prenatal care visit and delivery, scored in 4 categories: 1) Inadequate (received less than 50% of expected visits); 2) Intermediate (50%-79%); 3) Adequate (80%-109%); 4) Adequate Plus (110% or more). The information for the APNCU will be derived from either medical records or the birth certificate. The % of expected visits attended prior to study randomization will be included as a baseline covariate in analyses.

7.2.1.5 *The Short Opiate Withdrawal Scale (SOWS)-Gossop*

The SOWS-Gossop¹¹⁵ will be used to measure opioid withdrawal symptoms. The SOWS-Gossop, which is a self-administered scale that includes 10 items, rated on a scale of 0 (none) to 3 (severe), is a validated instrument with good reliability.¹¹⁶ It will be completed following the schedule in **Table 3**.

7.2.2 Infant Secondary Outcomes

7.2.2.1 *Other NOWS-related Outcomes*

Five additional NOWS-related outcomes will be abstracted from the medical record:

1. use of opioid medication for NOWS symptoms (yes/no); if yes, medication used;
2. infant hospital LOS defined as the infant's age, in days, at discharge;
3. use of adjunct medications (e.g., phenobarbital, clonidine);
4. NOWS scoring assessment used and peak score; and
5. an ICD-10 code indicative of NOWS (Yes/No); infants will be scored as "yes" if their medical record includes an ICD-10 code of P96.1 (neonatal withdrawal symptoms from maternal use of drugs of addiction) and/or P96.2 (withdrawal symptoms from therapeutic use of drugs in newborn) within the first 10 days of life.

7.2.2.2 *Discharge Outcomes*

Discharge outcomes to be abstracted from the medical record include: custody (e.g., mother, other relative, foster/adoptive family), medications at discharge (e.g., phenobarbital, clonidine), and an open case with child protective services (yes/no).

7.2.2.3 *Infant Development*

The 6- and 12-month versions of the Ages and Stages Questionnaire, third edition (ASQ-3)⁷¹ will be used to screen for developmental issues in the infants. The ASQ-3 is a validated, parent-administered screen used throughout the world⁷¹⁻⁷³ and deemed appropriate for assessing infants

exposed to opioids in utero.¹³ The outcome of interest is whether or not the infant scores below the ASQ-3 cut-off (yes/no). The ASQ-3 will be completed by the infant's caregiver, which may or may not be the birth mother. Thus, flexibility in the collection of this assessment will be allowed, including collection via mail. Infant development can be significantly impacted by psychosocial stressors and, thus, the individual completing the ASQ-3 will also be asked to complete The Family Psychosocial Screener (see **section 7.6.3**). Caregivers of infants scoring below the cut-off will be offered a referral for further evaluation.

7.3 Safety Measures of the Primary Objective

7.3.1 Adverse Events (AEs)

AEs will be assessed by study staff as outlined in **Table 3**. If an AE requires medical attention, it should be reported to a site MC immediately. For visits held via telemedicine or at an external location, research staff will contact a qualified medical clinician via phone to coordinate an assessment via telemedicine as quickly as possible; ideally this assessment will occur while the staff and participant are together at the external location. Recording of safety information, including Adverse Events, is described in **section 11.17**.

7.3.2 The Hospital Anxiety and Depression Scale (HADS)

The Hospital Anxiety and Depression Scale (HADS)¹¹⁷ will be used to assess for symptoms of depression and anxiety. The HADS is a brief, validated instrument that screens for both depression and anxiety¹¹⁸ and will be completed following the schedule outlined in **Table 3**. Participants who score in the range for possible depression (total depression score of 8 or higher) or anxiety (total anxiety score of 8 or higher) should be assessed by a qualified clinician before leaving the clinic as specified in the site clinical standard operating procedure (SOP). For visits held via telemedicine or at an external location, research staff will contact a qualified clinician via phone to coordinate an assessment via telemedicine as quickly as possible; ideally this assessment will occur while the staff and participant are together at the external location. If a participant is assessed and, at subsequent visits, continues to have the same elevated score, then the need for reassessment is at the discretion of a qualified clinician; a subsequent increase in the HADS score would require assessment by a qualified clinician.

7.3.3 Prior/Concomitant Medications

All medications taken by the participant since the start of her pregnancy and during the active study will be documented on a Prior/Concomitant Medications assessment (see **Table 3**). All medications taken by the participant while in the study should ideally be pre-approved by the MC whenever possible to avoid interactions with the study drugs.

7.3.4 Fetal Outcomes

Adverse fetal outcomes, including gestational age at time of outcome, will be abstracted from the medical record. These outcomes include: spontaneous abortions/miscarriages, stillbirth (i.e., death of a fetus at any time after the 20th week of pregnancy), pregnancy terminations and indications for termination (elective or medical and, if medical, the reason for termination).

7.3.5 Maternal Delivery Outcomes

Maternal delivery outcomes to be abstracted from the medical record include: cesarean section, abnormal fetal presentation during delivery, medical complications at delivery, and analgesic receipt during labor and delivery, postpartum, and upon discharge.

7.3.6 Birth/Neonatal Outcomes

Birth/neonatal outcomes will be abstracted from the medical record. These outcomes include: head circumference, weight and length at birth, gestational age at delivery, and 1-minute and 5-minute Apgar (activity, pulse, grimace, appearance, respiration) scores. Other outcomes will include: major birth defects, neonatal death, and need for resuscitation. Adverse birth outcomes will be characterized, including (if preterm), the reason for preterm birth (e.g., fetal distress, etc.). Other adverse neonatal outcomes will be captured including respiratory distress symptoms, need for respiratory support in the neonatal unit, feeding problems (need for nasogastric tube), seizures, and other co-morbidities.

7.3.7 Injection Site Examination

Participants will be asked to immediately report any injection site reactions to study staff for evaluation, monitoring, and possible referral, as needed. For weekly injections, the site of the last BUP-XR injection will be examined at the weekly Medication Check Visits. For monthly injections, the BUP-XR injection site will be examined at the weekly Medication Check Visit following the visit during which the injection was given. Injection site reactions will be documented on the Injection Site Reaction Reporting form.

7.3.8 Opioid Overdose Tracking

Some evidence suggests that women with OUD are at heightened risk for overdose during the postpartum period.²² During the study, the participant will complete a self-report assessment about opioid overdose as outlined in **Table 3**. If a participant reports an overdose, research staff will refer her to the clinic staff who will follow up each case as specified in the site clinical SOP. A self-reported overdose resulting in naloxone rescue will be collected as an SAE.

7.3.9 Infant Sedation

The limited data available has revealed low levels of BUP and BUP metabolites in the breastmilk of BUP-maintained women¹¹⁹ and breastfeeding is recommended for stable BUP-maintained women.¹²⁰ However, more data on potential infant exposure through breastfeeding is needed for BUP-maintained women and data on BUP/NX-maintained women⁶⁷ and BUP-XR-maintained women is lacking. While no adverse reactions are expected in breastfed infants in the present study, a theoretically possible and concerning adverse reaction, infant sedation, will be assessed via mother-report as outlined in **Table 3**. The infant sedation assessment will be completed by participants who are feeding their infants with breastmilk and/or formula and will assess for signs of infant sedation (e.g., not waking for feeding, difficulty breathing, etc.). In addition, if an infant sedation assessment in a breastfed infant meets the criteria of an SAE, it will be collected as an SAE, as all infant SAEs occurring in breastfed infants will be collected.

7.4 Covariates

There are a number of variables with the potential to impact mother-infant outcomes and, thus, either mask or exaggerate study medication effects. Randomization will help ensure that the BUP-XR and BUP-SL groups are balanced on these variables, however, they can still be an important source of variance. Analyses will control for these variables, referred to as covariates.

Pregnancy and Addiction Services Assessment (PAASA). Study site will be included as a covariate in the secondary analyses. As noted in **section 6.4.1**, all MOMs sites will use a collaborative care model but will likely differ in the specifics of the care model used (e.g., psychosocial treatment provided etc.), which could impact mother outcomes. A review of the

literature failed to identify an instrument for characterizing models of care for the management of pregnant women with OUD. Hence, an assessment was developed for use in this protocol, the PAASA, which will be used to characterize the treatment provided by the MOMs sites. The PAASA will also be used for the health economic analysis (see **section 10.9**); the PAASA data will likely need to be supplemented with data collected through semi-structured interviews (e.g., can be collected by e-mail correspondence, phone, or in-person interviews) for this purpose. In CTN-0080, a staff member from each site will complete the PAASA at two time-points (i.e., pre-site initiation and near the end of participant data collection).

7.4.1 Covariates for Mother Outcomes

Two covariates will be controlled for in the mother outcomes in addition to study site: 1) the use of other substances at baseline, which can impact both treatment adherence and illicit opioid use and 2) route of illicit opioid use (intravenous vs. not intravenous); the Phase 3 CAM2038 trial found that illicit use outcomes were significantly better for CAM2038, relative to BUP-SL, for participants with intravenous use.⁵⁹

7.4.2 Covariates for Infant Outcomes

The list of potential covariates for infant outcomes is provided in **Table 2**. The mother-related and infant-related covariates will be assessed in the process of collecting other outcome measures (e.g., UDS will capture substance use, including nicotine use, etc.) whereas the delivery hospital-related covariate needs to be obtained from the delivery hospitals; the BORN Survey will be used to obtain these data.

Table 2. Covariates for Infant Outcomes

<i>Mother-related Covariates</i>
Tobacco use ^{81, 121, 122}
UDS positive for: 1) substance of abuse; 2) illicit-opioids only ^{32, 80}
Exposure (yes vs. no) to psychiatric medications (e.g., antidepressants, benzodiazepines, gabapentin, etc.) during pregnancy ^{81, 123, 124}
<i>Infant-related Covariates</i>
EGA at delivery ^{81, 82}
Birthweight ^{81, 82}
Pharmacotherapy received for NAS/NOWS ^{125, 126}
Breastfed while in the hospital ^{127, 128}
NAS/NOWS scoring procedure utilized (e.g., Finnegan, Eat Sleep Console, other) ^{129, 130}
<i>Delivery Hospital-related Covariate</i>
Minimum days of observation for NAS/NOWS for infants exposed to long-acting opioids ¹³¹

BORN Survey. The Better Outcomes Through Research for Newborns (BORN) network of the Academic Pediatric Association created the BORN survey, which assesses hospital characteristics and all aspects of NAS/NOWS management.⁶² The BORN survey was recently used to assess practices for managing NAS/NOWS in BORN-affiliated hospitals; 76 hospitals, located in 34 states completed the BORN survey, with the results revealing significant diversity in approach across hospitals.⁶² The delivery hospital-related covariate in **Table 2** will be assessed by having a staff member from delivery hospitals meeting the criteria outlined in **section 6.4.1** (i.e., written protocol for NAS/NOWS management, etc.) complete the BORN survey at two time-points; staff will be reimbursed for their time. If a participant delivers at a different hospital than originally planned, an attempt will be made to obtain a completed BORN survey for the hospital if one has not been obtained previously.

7.5 Health Economic Measures of the Tertiary Objective

The main economic outcome will be the incremental cost-effectiveness ratio (ICER), calculated as the incremental cost of BUP-XR relative to BUP-SL, divided by the incremental effectiveness of BUP-XR relative to BUP-SL. The main measure of effectiveness will be QALYs. The secondary measure of effectiveness will be Abstinence Years (a measure of time abstinent). The QALY is a measure that combines the HRQoL associated with an individual's health state and their time spent in that state, and is recommended as the main effectiveness measure in economic evaluation studies due to its ability to be compared across interventions and disorders, thereby enabling a broader economic interpretation.¹³² In addition, generally accepted thresholds for defining value have been established for QALYs, unlike clinical measures.^{133, 134} Also, HRQoL is increasingly recognized as a key indicator of patient well-being that is not captured in clinical measures.^{135, 136} Time abstinent is an important measure of effectiveness for clinical stakeholders, and calculating cost-per-Abstinent-Year enables comparisons with existing economic evaluations that have utilized similar effectiveness measures, especially those that have relied solely on time abstinent measures.⁹⁴

7.5.1 Healthcare Service Utilization

The utilization of healthcare services will be measured using medical records, the Treatment Services Review (see **section 7.6.3**), and the Non-study Medical and Other Services (NMOS) form, which includes items assessing utilization of therapy for issues other than SUD, out-of-pocket healthcare expenditures, and type of insurance (if any). Healthcare services will include OUD treatment medications, residential and outpatient SUD treatment days; hospital SUD detoxification days; mental health treatment visits; and non-SUD inpatient, outpatient, and emergency department visits. The reliability and validity of self-reported data is well established over recall periods similar to those in our study.¹³⁷ The NMOS form has been successfully used in prior economic evaluations,^{138, 139} including alongside CTN trials.^{140, 141}

7.5.2 Health-related quality of life

Health-related quality of life (HRQoL) will be measured using the Patient-Reported Outcomes Measurement Information System (PROMIS).^{142, 143} PROMIS was developed using item response theory, with support from the National Institutes of Health. Because of its foundation, PROMIS is able to improve upon common deficiencies of existing, widely-used, HRQoL instruments capable of generating a single health utility index value for the calculation of QALYs^{144, 145, 146, 147} including: floor and ceiling effects among participants who are especially ill or healthy, respectively, and imprecise questions that blend concepts.¹⁴⁸ The PROMIS-Preference (PROPr) scoring system uses the respondent's scores for each of the following PROMIS domains to calculate a health utility index value that represents the general US population's preference for the respondent's current health state: Cognitive Function–Abilities, Depression, Fatigue, Pain Interference, Physical Function, Sleep Disturbance, and Ability to Participate in Social Roles and Activities.^{149, 150} PROMIS has 5 levels for each domain: no problems, slight problems, moderate problems, severe problems, and extreme problems. The health-utility value produced by PROPr can range from -0.022 to 1, where 0 represents death, 1 represents perfect health, and values below 0 represent states perceived to be worse than death. Construct validity for PROPr has been demonstrated using other HRQoL instruments and two large datasets from the general US population.¹⁴⁸ The health-utility value is then used to calculate QALYs, as our team, and many others have done in similar studies.^{94, 138, 140, 141, 151}

7.5.3 Abstinent Year

The abstinent year will be operationalized as the predicted proportion of the year that the participant was abstinent from opioids. Opioid abstinence will be calculated using urine testing as described in **sections 7.1.1** and **7.1.2**.

7.6 Other Measures

7.6.1 Screening Assessments

Pre-screen Interview: The pre-screen interview includes questions about pregnancy status, plans for treatment, and substance use.

PhenX Tier 1: The PhenX Tier 1 of the Substance Abuse and Addiction core¹⁵² will be used to collect information on demographic characteristics (e.g., sex, age, ethnicity, etc.) and information on recent and lifetime use of tobacco, alcohol, and other substances.

The DSM-5 Checklist: The DSM-5 Checklist is a semi-structured, interviewer-administered instrument that will be used to assess for DSM-5 substance use disorders including: opioid, alcohol, amphetamine, cocaine, cannabis, and sedative. It will be completed during screening/baseline.

Suicidal and Homicidal Screening Form (PRISM): The Suicide and Homicide Screening Form is a structured, reliable interview modified from the Psychiatric Research Interview for Substance and Mental Disorders- PRISM¹⁵³ and will be completed by study staff during screening/baseline. A qualified mental health professional must assess participants reporting current suicidal/homicidal intent as specified in the site clinical SOP. For visits held via telemedicine or at an external location, research staff will contact a qualified clinician via phone to coordinate an assessment via telemedicine as quickly as possible; ideally this assessment will occur while the staff and participant are together at the external location.

Blood Chemistry: Clinical labs need to be reviewed during screening/baseline to assess eligibility. Results from labs completed within 30 days before consent can be utilized for this purpose. Otherwise, blood will be collected in serum separation evacuated venous blood collection tubes. Quantitative analysis will be performed, which will include the following analytes: glucose, creatinine, alanine aminotransferase (ALT/SGPT), aspartate aminotransferase (AST/SGOT), total bilirubin, and blood urea nitrogen (BUN). A prescription topical numbing cream may be offered to all participants prior to the blood draw.

Pregnancy Test: A urine pregnancy test designed to measure human chorionic gonadotropin hormone will be completed during screening/baseline to confirm the participant's pregnancy status.

Estimated Gestational Age (EGA): If available, EGA will be abstracted from the medical record. Ideally, EGA will be defined based on an ultrasound completed as part of routine prenatal care. However, if an ultrasound is not available, then EGA will be based on last menstrual period (LMP), which has been shown to have good concordance with ultrasound results.¹⁵⁴ In the case where EGA based on ultrasound is not available prior to randomization but is available later, the EGA for randomization will be based on LMP and will be compared to the ultrasound-based EGA to ensure that the proper randomization indicator (6 weeks -18 weeks vs. 19 weeks - 30 weeks) was used.

Treatment and Research Status: The Treatment and Research Status form will be used to assess study candidates' status on study inclusion/exclusion criteria related to OUD treatment (e.g., enrolled in treatment, etc.), plans for delivery (e.g., planned delivery hospital), and research participation. In addition, information regarding pressure to attend treatment, which can be related to substance use outcome, will be assessed.

Medical and Psychiatric History: A site MC will obtain a medical and psychiatric history from the participant covering past and present health conditions to help determine eligibility and to provide baseline information.

Drop-out Risk Assessment: The Drop-out Risk Assessment form, which was used in CTN-0052, will be used to assess study candidates' status on the exclusion criterion of being unlikely to complete the study protocol (e.g., due to relocation from the clinic area, probable incarceration, etc.).

7.6.2 Sample Characteristics

Pregnancy-history characteristics: Pregnancy history (e.g., gravidity, parity, etc.) will be assessed by self-report and medical record data, as available, with medical record data being the preferred data source.

HIV/Hepatitis C status: HIV and Hepatitis C status will be assessed by self-report and medical record data, as available, with medical record data being the preferred data source.

Trauma history: Exposure to traumatic events is elevated in women with SUDs and is associated with worse treatment outcomes.¹⁵⁵ The Trauma History Screen is a brief, self-administered instrument with good reliability and validity.^{156, 157} The Trauma History Screen will be used to assess the participant's exposure to 14 traumatic events and the severity and duration of the emotional response to any event experienced.

Psychosocial status: The Trauma History Screen does not assess intimate partner violence, which is fairly prevalent in women with OUD, and, thus, will be supplemented with two items that have been used to assess intimate partner violence in past research.¹⁵⁸ In addition, other characteristics of interest, including living arrangements, pregnancy intention, and number of children and their custody will be assessed.

Maternal depression: The Patient Health Questionnaire-9, will be used to assess for symptoms of major depression.¹⁵⁹ It will be completed following the schedule in **Table 3**. A qualified mental health professional must assess participants reporting current suicidal intent as specified in the site clinical SOP.

Fagerström Test for Nicotine Dependence: Approximately 90% of pregnant women receiving opioid maintenance treatment smoke cigarettes,¹⁶⁰ which is associated with worse pregnancy outcomes and NAS/NOWS.^{121, 122} The Fagerström is a brief self-administered assessment of cigarette use patterns,¹⁶¹ which yields a single overall dependence score.

The Timeline Followback (TLFB) procedure:^{162, 163} will assess the participants' self-reported use of substances for the 30 days before study consent.

Thoughts about Abstinence: The Thoughts about Abstinence assessment,¹⁶⁴ which assesses desire to quit, expected success in quitting and estimated difficulty in avoiding relapse, has been found to be predictive of treatment response in pregnant substance users.¹⁶⁵ It will be completed for alcohol, drugs, and cigarettes following the schedule outlined in **Table 3**.

Opioid Overdose Risk Survey: This survey assesses factors, including having experienced an opioid overdose, that are associated with an increased risk of experiencing an opioid overdose.¹⁶⁶

Marijuana Use Assessment: This survey assesses the participant's recreational and medical marijuana use frequency over the past 12 months, including reasons for use (e.g., to address medical/psychological concerns, to replace other substances or medications), method of administration, and perceived harm or benefit associated with use.

7.6.3 General Measures

Treatment Services Review: The addiction-related treatment services received by participants during the prior 28 days will be assessed with the use of the Treatment Services Review, Version 6¹⁶⁷ according to the schedule in **Table 3**. CTN-0080 will utilize the version of the instrument created for use in CTN.

The Family Psychosocial Screener: A number of psychosocial stressors can impact infant development, including maltreatment, parental mental health, and domestic violence.^{168, 169} The Family Psychosocial Screener includes components designed to evaluate parental depression, intimate partner violence, parental history of abuse, and a number of other risk factors for developmental problems.¹⁷⁰ During initial development, it was shown to identify significantly more mothers with low self-esteem, depression, and history of abuse as a child than simply reviewing medical records.¹⁷¹ The instrument is a self-administered questionnaire that typically takes ≤10 minutes to complete. It will be completed by the individual completing the ASQ-3 at 6 and 12 months.

Pregnancy Test: During the postpartum phase, a urine pregnancy test will be completed prior to medication administration for BUP-XR participants receiving the monthly formulation. Additionally, a urine pregnancy test will be completed if the participant self-reports a new pregnancy.

7.7 Administrative Forms

Locator Form(s): A locator form is used to obtain information to assist in finding participants during treatment and at follow-up. This form collects contact information including the participant's current address, email address, phone numbers, and social media contact information. In order to facilitate locating participants if direct contact efforts are unsuccessful, addresses and phone numbers of family/friends who may know how to reach the participant are collected, as well as additional participant information such as social security number, driver's license number, and other information to aid in searches of public records. This information will be collected as outlined in **Table 3**. The updating of this form may occur during visits at the clinic or via telemedicine. For visits occurring off-site, research staff will contact the participant before or after the visit to update the form via telemedicine. In the event that the participant does not retain custody of her infant, an additional locator form may be obtained from the guardian. No information from locator forms is used in data analyses.

Study Eligibility: This form, which lists all the study inclusion and exclusion criteria, must be completed for every participant who has signed informed consent and entered the Screening/Baseline phase. Eligibility is assessed on an ongoing basis during the screening phase. This form is to be completed in the data system prior to randomization. Eligible participants will be randomized; ineligible participants will be excluded and deemed screen failures.

Study Completion: This form, which indicates that the participant has formally terminated his/her study involvement, must be completed for every participant who has been randomized into the study. The purpose of the Study Completion Form is to document: 1) the date on which a

randomized participant attended her final study visit, 2) whether the participant completed the study or ended study involvement prematurely, and 3) if the participant ended study involvement prematurely, the reason why that occurred. This form also provides a location for the site PI attestation of review of all study data.

Missed Visit and Visit Documentation: This form is designed to capture the reason a study visit was missed, the location(s) in which the visit occurred and if assessments occurred outside of the expected window. For missed visits, once the visit window closes without completion of the visit, this assessment will be completed directly in the electronic data capture system. Completing this form will remove the requirement for all assessments scheduled for that visit. Active tracking and follow-up should be performed for all missed visits. For visits that occur, this assessment will be completed directly in the electronic data capture system once the visit is complete to ensure all locations and out-of-window assessments are documented.

End of Medication: This form is completed for all randomized participants. If a participant permanently discontinues study medication during the trial, the reason(s) for discontinuation will be captured. In cases where participants discontinue study medication to transfer to an alternative treatment (e.g., methadone, extended-release naltrexone, BUP from another provider) a release of information will be obtained to confirm treatment engagement.

Protocol Deviation: This form should be entered into the electronic data capture system whenever a protocol deviation occurs. This form will document a description of the deviation, how it occurred, the corrective action taken to resolve the specific deviation, as well as a description of the plan implemented to prevent future occurrences of similar deviations.

Mental Health Follow-up Assessment: This assessment must be completed by a qualified clinician if the participant endorses suicidality on the PHQ-9 and/or either suicidality or homicidality on the PRISM or has a HADS score of 8 or higher on depression or anxiety subscales. In addition, this form will be completed each time an assessment of suicidality/homicidality occurs due to spontaneous participant report during the study. The completion of the Mental Health Follow-up Assessment form requires direct evaluation of the participant for suicide/homicide risk by a qualified mental health professional according to the site's specific SOP. This evaluation will ideally take place prior to the participant leaving the study visit. For visits held via telemedicine or at an external location, research staff will contact a qualified clinician via phone to coordinate an assessment via telemedicine as quickly as possible; ideally this assessment will occur while the staff and participant are together at the external location.

7.8 Conceptual Model Assessments of the Secondary Objective

Randomized participants will be offered the opportunity to participate in the conceptual model assessment (CMA) sub-study (see **section 8.9**), which will provide the data needed to test the MOMs conceptual models (see **section 4.4**). Participants signing informed consent for the CMA sub-study will ideally provide the measures described below. Several measures involve the collection of blood samples; for all blood samples the level of buprenorphine and its metabolites (norbuprenorphine, buprenorphine-glucuronide, and norbuprenorphine-glucuronide) will be assessed.

1. **Maternal C_{min} at study weeks 3 and 5.** Participants will be scheduled for their study week 3 and 5 visits at the time corresponding with their C_{min} . For BUP-XR participants, a blood sample will be taken right before the administration of the BUP-XR dose. Participants in the BUP-SL arm will have their blood sample drawn prior to taking their (first) BUP-SL dose for the day. The time and date of the most recent medication dose will be assessed

based on dosing record (BUP-XR) or self-report (BUP-SL). As permitted by institutional policies and local regulations, staff may complete these blood draws at a remote laboratory and/or community location; alternately sites may contract for phlebotomy/laboratory services to perform these draws.

2. Fetal Assessment at ~36 weeks EGA. The peak-trough effects for BUP-SL increase with increasing EGA²⁴ and, thus, the timing of this assessment will be at approximately 36 weeks EGA; this timing should increase the likelihood of observing BUP effects while helping to ensure that the majority of participants are still pregnant. The fetal assessment, consisting of a non-stress test (NST) and biophysical profile (BPP), will be obtained at approximately C_{max} , which is when the BUP effect on the fetus is most likely to be observed. For BUP-SL participants, the monitoring session will occur approximately 2.5 hours after dosing. For BUP-XR participants, the monitoring session will occur approximately 24 hours after injection.²⁹ The NST will use Doppler measurement to assess fetal heart function over a continuous observation period of ≥ 20 minutes.¹⁷² The BPP will use ultrasound imaging over a 30-minute period to determine a total score (range: 0-10) based on five parameters: 1) a reactive NST; 2) two or more gross body movements; 3) one or more episodes of limb or hand flexion and extension (muscle tone); 4) breathing movements lasting at least 20 seconds; and 5) a normal amniotic fluid volume index (5-24 cm for the 4 quadrant total).¹⁷² As noted in **section 4.4**, the variable of most interest is fetal heart rate variability (FHRV) at ~36 weeks EGA. Fetal heart rate accelerations, a measure of episodic FHRV,^{24, 69} will be used as the FHRV measure for MOMs. Jansson et al. recently reported that FHR accelerations at ~36 weeks EGA were significantly greater in number at BUP trough, relative to BUP peak.²⁴ In a secondary analysis of data from the MOTHER trial, Salisbury et al.¹⁷² reported significantly more FHR accelerations for women maintained on BUP-SL, relative to women maintained on methadone, at EGA ~32 weeks. Information about any action specifically taken as the result of the CMA fetal monitoring will be collected. While some sites may be equipped to perform this assessment in-clinic, it is likely that this assessment may occur at other clinical sites either within the institution or at an external clinical site providing these services.
3. Maternal peak-to-trough fluctuation at ~36 weeks EGA. Two blood samples will be taken from participants at approximately 36 weeks EGA, roughly corresponding to C_{max} and C_{min} . The participants will have been taking BUP for a minimum of approximately 6 weeks and so will have reached steady state. Peak-to-trough fluctuation will be calculated as the ratio of C_{max} to C_{min} . The time and date of the most recent medication dose prior to each blood sample will be assessed based on dosing record (BUP-XR) or self-report (BUP-SL). As permitted by institutional policies and local regulations, staff may complete these blood draws at a remote laboratory and/or community location; alternately sites may contract for phlebotomy/laboratory services to perform these draws.
4. Cord and maternal plasma BUP/BUP-metabolite and cotinine levels. Cord plasma is relatively easy to collect and does not require maternal consent.¹³ BUP metabolites in cord blood have been found to be predictive of NAS/NOWS severity.⁸² Cord cotinine levels reflect tobacco exposure stemming from both first and secondhand smoke exposure¹⁷³ and will be used as the prenatal nicotine exposure covariate for CMA analyses if available. Maternal plasma will be obtained to evaluate the association between maternal BUP/BUP-metabolite levels and NOWS-related outcomes. These samples will be collected at the delivery hospital.

7.9 Infant Neurodevelopmental Outcomes of the Quaternary Objective

Infant caregivers will be offered the opportunity to participate in the infant neurodevelopmental outcomes (INO) sub-study (see **section 8.10**). Individuals signing consent will participate in the assessments listed below. In addition, a locator form (see **section 7.7**) will be completed at the 12-month assessment to facilitate retention at the 24-month assessment.

Demographics. The demographics questions from the PhenX toolkit will be utilized.

BayleyTM-4. The BayleyTM-4¹⁰² is considered the gold standard assessment of early child development and includes cognitive, language, fine motor, and gross motor subscales. The BayleyTM-4 will be used to evaluate infants at the 12- and 24-month assessments by a certified examiner who is blind to the CTN-0080 participant's treatment arm. The main outcome is the score on the cognitive subscale at the 24-month assessment. While some sites may be equipped to perform this assessment in-clinic, it is likely that this assessment may occur at other clinical sites either within the institution or at an external clinical site providing these services. As determined by the provider, it is permissible for this assessment to be administered as a home visit.

Child Behavior Checklist (CBCL). The CBCL¹⁷⁴ is completed by caregivers and includes items that describe behavioral, emotional, and social problems that characterize preschool children. The CBCL is the measure used by the National Institute of Child Health and Human Development Neonatal Research Network to assess problem behaviors at the 22-26-month visit and will be collected at the 24-month assessment in the INO. Flexibility in the collection of this assessment is allowed including collection via mail.

8.0 STUDY PROCEDURES

8.1 Study Overview

Many of the CTN-0080 outcomes will be abstracted from medical records. For each participant, these records will be obtained from several institutions including, but not limited to: 1) the study site's treatment program, 2) the participant's OB provider, and 3) the participant's delivery hospital. Releases to access these records will be obtained as outlined in **Table 3** and will be used to access the medical records for all participants, including study dropouts, unless the participant explicitly withdraws consent. To streamline data collection, the medical records will serve as source documents, with research staff transcribing the required information onto study case report forms (CRFs). The schedule of research visits and research assessments for all participants are delineated in **Table 3**. **Table 5** provides an overview of the CMA sub-study procedures and assessments. **Table 6** provides an overview of the INO sub-study procedures and assessments. While ideally all main study visits will occur at the participating clinic, alternate arrangements may be made at the site's discretion to accommodate participant needs and safety concerns. In accordance with the site's institutional policies and procedures, study visits may occur at other locations affiliated with the institution or elsewhere in the community (including, but not limited to, home visits or visits at non-affiliated community healthcare/laboratory sites), or via remote contact, such as by telephone or other institutionally-approved telemedicine mechanisms. Some assessments may be completed remotely and mailed/shipped to the study team; still others may involve allowing the participant to access the participant self-report data collection system remotely on non-study specific electronic devices using a secure login. CMA and INO procedures may also occur at other locations to accommodate participant and/or provider needs and preferences. All visits occurring outside of the primary research study site will be managed in such a way that there is no increased risk to participant safety.

8.2 Participant Recruitment, Pre-screening, and Consent

Potential participants will be primarily recruited from intakes at participating sites. Advertisements may be used, as needed, but all participants must have completed intake at a study site to be eligible for randomization. Interested candidates will complete a pre-screen, ideally prior to their intake/scheduled clinic visit. The pre-screen will include questions about pregnancy status, past drug use, plans for treatment, and general health status. Candidates who pass the pre-screen will be scheduled for administration of the written consent procedure and a subsequent screening visit. The consent procedure will occur during a live interaction between the candidate and study staff; however, this interaction may occur face-to-face at the study site or at another approved location, or via telemedicine in accordance with institutional policies. If still interested after receiving an explanation of the study, the candidate will be given an opportunity to review, inquire about, and sign the informed consent form. Any participant who has difficulty understanding the information contained in the consent form will be asked to review the misunderstood portion(s) of the consent and discuss them with a research staff member until she shows complete understanding of the information and may thus give full consent. Research staff members will work closely with the study candidates in an effort to help them understand the requirements of their participation. Persons with literacy problems will be assisted to the extent possible. Any participant who is unable to demonstrate understanding of the information contained in the informed consent will be excluded from study participation. In the event that the consent procedure occurs via telemedicine, the candidate will provide consent via a HIPAA-compliant electronic system or will be provided with a prepaid shipper/envelope for returning the signed consent to the study team. No other study procedures will occur until the signed consent is received back from the candidate.

8.3 Screening/Baseline

After signing the informed consent form, the study participant will proceed through the screening/baseline phase. Ideally, the screening/baseline procedures will be completed within a week, but the allowable time for completion is within 28 days of signing consent.

8.4 Randomization Plan

Eligible participants will be randomized in a 1:1 ratio to BUP-XR or BUP-SL. The randomization process will be performed by computer by the Data and Statistics Center (DSC). A permuted block randomization procedure with random block sizes will be implemented to balance on site, whether participants are on BUP-SL at the time of randomization (yes vs. no), and EGA at time of randomization (6 weeks - 18 weeks vs. 19 weeks - 30 weeks); EGA was used as a stratification variable in the MOTHER trial.⁴³

Notes: ¹Can be completed in multiple visits; ² Randomization will typically occur as part of a screening/baseline visit; ³ Number of visits depends on EGA at randomization and delivery; ⁴The 12 month research visit includes the assessment of AEs/SAEs, injection site examination, urine collection, and the infant sedation assessment; ⁵completed via medical record abstraction; ⁶Will be done for the study if not available from medical record; ⁷These visits will occur approximately once per week in accordance with BUP-XR administration windows; ⁸Participants who breastfeed will receive the weekly formulation; ⁹Dispensing frequency at clinician discretion; ⁹May be completed as part of a research visit or outside of a visit (e.g., mailing).⁺ are not collected in Advantage eClinical

8.5 Active Treatment Phase

The active treatment phase includes the time during which participants are pregnant (the length of which will depend on the EGA at enrollment and the timing of delivery) through approximately 12 months postpartum. During this time, participants in both treatment conditions will participate in the SUD treatment services typically offered by the site. Participants will receive BUP-XR or BUP-SL as outlined in **section 9**. Participants in both conditions will meet with study staff in person or remotely to complete study assessments as outlined in **Table 3**. For participants taking monthly BUP-XR, the last administration/dispensing of the medication will be scheduled for approximately week 49 of the postpartum phase. For participants taking the weekly BUP-XR formulation, the last administration will be scheduled for approximately week 52. Dispensing frequency for BUP-SL (BUP/NX-SL) is at the clinician's discretion. The 12-month research visit will be scheduled for week 53, which will allow the assessment of the participant's medication adherence and any potential adverse events throughout the entire 12-month postpartum period. Participants who are terminating early but are willing to attend an additional visit should complete the assessments that would have been completed at the next scheduled research visit.

8.6 Participant Reimbursement

Participants will be reimbursed for their transportation, inconvenience, and time. The form of this reimbursement will be determined by the study sites. As noted in **Table 3**, the number of visits during pregnancy will depend on the EGA at randomization and the timing of delivery. The number of weekly Medication Check Visits that do not coincide with a research visit and, thus, for which participants will be reimbursed to help cover transportation costs, are estimated to range from 7-36 visits. The estimated potential range of research monthly visits is 2-8. The recommended reimbursement schedule for participant visits and completion of infant-related assessments is provided in **Tables 4a** and **4b**, respectively. The reimbursement amounts listed in Table 4a will be reduced by \$10 if the study participant does not travel to attend the visit.

Table 4a: Reimbursement schedule for participant research visits

Visit	Total per Visit (\$)	Total # of Visits	Grand Totals (\$)
Screening/baseline			\$120
Week 3 visit	\$40	1	\$40
Weekly Medication Check visits during pregnancy*	\$20	7 - 36	\$140 - \$720
Monthly Research visits during pregnancy	\$60	2 - 8	\$120 - \$480
Weekly Medication Check visits postpartum*	\$20	48 - 52	\$960 - \$1040
Postpartum Research visits (1, 3, 6, 9 months)	\$60	4	\$240
Postpartum visit month 12	\$70	1	\$70
Total			\$1,690 - \$2,710

*Not coinciding with a research visit

Table 4b: Reimbursement schedule for infant-related assessments

Visit	Total per Visit (\$)	Total # of Assessment Points	Grand Totals (\$)
6-month postpartum assessments	\$30	1	\$30
12-month postpartum assessments	\$30	1	\$30
Total			\$60

8.7 Medication and Trial Discontinuation

8.7.1 Medication Discontinuation

An investigator may discontinue a participant's medication if he or she deems it clinically appropriate or, at the discretion of the investigator, for any of the reasons listed below.

1. significant side effects that are likely to have been caused by the study medication
2. serious or unexpected AEs which would make further study medication dosing not in the participant's best interest
3. inability or unwillingness of the participant to comply with the study protocol
4. serious illness

A participant may discontinue medication anytime she wishes. Although the participant may withdraw entirely from the study whenever she wishes, she will be strongly encouraged to continue attending visits at which safety measures are scheduled to be assessed.

Study participants withdrawn from the protocol secondary to a medical or psychiatric concern will be referred for appropriate treatment. Participants will be asked to sign a general consent for the release of information to the referred health care provider. Study staff may request transportation for emergency treatment of a participant if medically appropriate (e.g., for acutely psychotic or suicidal participants).

8.7.2 Trial Discontinuation

The study sponsor has the right to discontinue the investigation at any time.

8.8 Access to Treatment After Study Completion

Prior to the 12-month postpartum visit, the research staff will make an effort to arrange for continued treatment with BUP as appropriate within the community. Where this is not possible (due to insurance or availability of treatment resources, etc.), alternative treatment referrals (e.g., methadone maintenance, intensive outpatient psychosocial aftercare, etc.) will be made as appropriate. For participants who do not wish to continue, or for whom community resources are not available, the study will provide up to a two-week BUP-SL taper.

8.9 Conceptual Model Assessments (CMA) Sub-study

8.9.1 Overview

Participants will be invited to participate in the CMA sub-study, which will be used to evaluate the MOMs conceptual models. The CMA includes some assessments that can be readily obtained by study site staff or by clinical/laboratory staff hired by the site to perform these blood draws (e.g., blood draws for C_{max} and C_{min}). The completion of the fetal assessment will likely require the study site to establish a collaboration with an OB clinic capable of completing the fetal assessment. The collection of the cord and mother plasma samples at delivery will need to be coordinated with the delivery hospital. While it would be ideal to have all assessments completed for all participants in the CMA sub-study, feasibility issues may make this difficult for some participants. An overview of CMA assessments and procedures is provided in **Table 5**.

Table 5. Overview of CMA Assessments and Procedures							
	Time*	Pregnancy					Delivery
Research Visits:	Scrn	Wk 3	Wk 5	36 Weeks EGA (1)	36 Weeks EGA (2)	36 Weeks EGA (3)	
Informed Consent	15						
Blood collection for C_{min}		10	10			10	
Blood collection for C_{max}					10		
Fetal Assessment (NST, BPP)				70			
Fetal Monitoring Action*							
Maternal blood collection							X
Cord blood collection							X
Total Time (min)	15	10	10	70	10	10	
Compensation	-	\$25	\$25	\$85	\$25	\$25	

*Estimated time for participants to complete the assessment/procedure; *Any action taken specifically as a result of the CMA fetal monitoring will be documented.

The reimbursement amounts listed in Table 5 will be reduced by \$10 if the study participant does not travel to attend the visit.

8.9.2 Recruitment and Consent

Recruitment for the CMA sub-study will ideally be initiated when a potential participant passes pre-screening for MOMs. The first CMA assessment is scheduled to occur at the study week 3 visit and so the consent will, ideally, be discussed during screening/baseline so that interested participants can be scheduled for the study week 3 visit at a time corresponding to their C_{min} . However, a participant can join the CMA sub-study at any time through her delivery.

8.9.3 Visits for the CMA Sub-study

When possible, the CMA visits will occur in conjunction with the research visits (see **Table 3**). The first two CMA visits, during which blood is collected at C_{min} , are expected to occur in conjunction with the study week 3 and 5 visits. Three separate CMA assessments will be obtained at approximately 36 weeks EGA. One assessment will be completed at sites responsible for completing the fetal assessment, which may be a study site, or may be another clinical site that provides these services. Participants will complete the fetal assessment when they should be at approximately BUP C_{max} (i.e., roughly 24 hours following BUP-XR injection and 2.5 hours following BUP-SL dose). The second assessment is a blood draw for C_{max} ; ideally this blood draw will occur concurrently with the fetal assessment, but may occur on a different day within the 36 weeks EGA timeframe. The third assessment is a blood draw which will ideally occur in conjunction with the research or clinical visit closest to 36 weeks EGA and at a time corresponding to BUP C_{min} .

8.10 Infant Neurodevelopmental Outcomes (INO) Sub-study

8.10.1 Overview

Infant caregivers will be offered the opportunity to participate in the infant neurodevelopmental outcomes (INO) sub-study. An overview of assessments and procedures is provided in **Table 6**.

The INO data will be locked separately from the rest of the CTN-0080 database to allow CTN-0080 database lock following collection of the final (non-INO) CTN-0080 data point.

Table 6. Overview of INO Assessments and Procedures		
	12-month assessment ⁺	24-month assessment ⁺
Informed Consent	15	
Demographics	5	5**
Locator Form	5	
Bayley™-4	90	120
CBCL		10
Total Time (min)	115	130-135**
Compensation	\$100	\$150

⁺ Estimated time for participants to complete the assessment/procedure.

^{**} Demographics will be collected if caregiver changes.

The reimbursement amounts listed in Table 6 will be reduced by \$10 if the study participant does not travel to attend the visit.

8.10.2 Recruitment

The participant in the INO sub-study will be the infant's caregiver, which may or may not be the CTN-0080 participant; hence, recruitment for the INO sub-study will typically occur postpartum. Recruitment of infant caregivers who are not the infant's biological mother will include providing information about the INO sub-study in conjunction with the collection of the ASQ-3s.

8.10.3 INO Visits

At the initial study visit, when the infant is approximately 12 months of age, interested caregivers will complete the informed consent process, provide demographic information, including information about socioeconomic status, and will provide locator information to aid retention efforts for the 24-month assessment. The Bayley™-4 will be administered at both visits. While some sites may be equipped to perform the Bayley in-clinic, it is likely that this assessment may occur at other clinical sites either within the institution or at an external clinical site providing these services. As determined by the provider, it is permissible for this assessment to be administered as a home visit.

In addition, at the 24-month assessment, the CBCL will be administered to the caregiver. Flexibility in the collection of the CBCL is allowed, including collection via mail.

If the caregiver changes between the 12-month and 24-month time period, demographic information will be collected a second time.

9.0 STUDY MEDICATIONS

At present, states vary in the extent to which they cover the cost of BUP treatment for pregnant and postpartum women, with some states covering the cost through one year postpartum and others covering only pregnancy. CTN-0080 seeks to evaluate the effectiveness of BUP-XR, relative to BUP-SL, under a model in which states would universally cover the cost of BUP treatment through 12 months postpartum. Given the variability in state coverage, this can only be achieved by providing BUP-XR and BUP-SL at no cost to study participants. Medication will be obtained by National Institute on Drug Abuse (NIDA) or a NIDA contractor for distribution to the sites.

9.1 BUP-XR (CAM2038)

BUP-XR comes in several doses in both the once weekly and once every 4-week (monthly) formulations to allow for individualized medication plans (see **Table 7**). They are small volume injections that come in prefilled syringes with a safety device that can be stored, unrefrigerated, and administered subcutaneously with a thin needle. The target doses will be 24 mg for the weekly formulation and 96 mg for the monthly formulation, but the actual dose may be lower or higher as determined by the prescribing clinician (e.g., based on craving/withdrawal experienced by the participant, etc.).

Table 7. BUP-SL dose and approximate equivalent weekly and monthly BUP-XR injections

BUP-SL	BUP-XR weekly	BUP-XR monthly
<6 mg	8 mg (0.16 mL)	--
8-10 mg	16 mg (0.32 mL)	64 mg (0.18 mL)
12-16 mg	24 mg (0.48 mL)	96 mg (0.27 mL)
18-24 mg	32 mg (0.64 mL)	128 mg (0.36 mL)

Note: For a BUP-SL dose >24 mg there is no equivalent BUP-XR dose available for CTN-0080.

9.2 BUP-SL

Sites will be provided with the BUP-SL product(s) that they request. Sites requesting the mono-buprenorphine product will be provided with 2 mg and 8 mg buprenorphine tablets. Sites requesting the combination product will be provided with buprenorphine/naloxone film in 4 mg/1mg and 8mg/2 mg buprenorphine/naloxone doses. Sites may request both forms of BUP-SL (e.g., mono-buprenorphine product for use during pregnancy and combination product for use during the postpartum phase). The target dose will be 16 mg daily, which is consistent with SAMHSA's recommended dose during pregnancy,¹³ but the actual dose may be lower or higher as determined by the prescribing clinician (e.g., based on craving/withdrawal experienced by the participant, etc.). A dose of up to 32 mg of BUP-SL daily, which is used in clinical practice, is allowed. While the maximum dose of BUP-XR is equivalent to 24 mg of BUP-SL (see **Table 7**), allowing up to 32 mg in the BUP-SL arm is consistent with utilizing pragmatic study features where feasible. It should be noted that potential participants who are prescribed 32 mg of BUP-SL daily prior to randomization might not be good candidates for the study because of the lack of an equivalent BUP-XR dose.

9.3 Dispensing Study Medication

Study medications will be provided at no cost to the participants. BUP-XR will be administered by study staff with appropriate licensure and training at induction and approximately every week during pregnancy. During the postpartum phase, women who are breastfeeding will continue

receiving BUP-XR weekly while women who are not breastfeeding may receive BUP-XR every four weeks; a possible exception is continued weekly BUP-XR for women who are not breastfeeding but for whom the prescribing clinician determines that 8 mg is the appropriate dose. Participants transitioning to monthly BUP-XR will be given the dose equating to their BUP-XR weekly dose (see **Table 7**). CAM2038 should be injected slowly into the subcutaneous tissue of the upper arm, abdomen, buttock or thigh. CAM2038 should not be administered in the same location for a minimum of 8 weeks for the weekly injection. No injection site rotation is needed for the monthly injection. BUP-XR must be dispensed/administered by a licensed medical practitioner appropriately trained and authorized to dispense study medications per local regulations. Dispensing frequency for BUP-SL (BUP/NX-SL) is at the clinician's discretion.

Participants who are discontinued, who do not wish to continue, or for whom community resources to continue are not available, the study may dispense sufficient BUP-SL for up to a two-week taper beginning at any time during treatment. All study medications shall be prepared and dispensed by a pharmacist or licensed medical practitioner appropriately trained and authorized to dispense study medications per local regulations.

9.3.1 Induction

Following randomization, participants will be inducted onto their assigned pharmacotherapy. Guidelines for induction are provided in the study operations manual.

BUP-XR assignment: Research suggests that participants already being treated with BUP-SL can safely be given the corresponding dose of BUP-XR (see **Table 7**).¹⁷⁵ For participants not being treated with BUP-SL, sites will utilize the induction setting (e.g., outpatient, inpatient, or other in-person setting such as home visit or community clinical location) being used by the clinic for BUP-SL. It should be noted that precipitated opioid withdrawal following BUP-XR administration is not expected for several reasons. First, precipitated withdrawal was not observed in the CAM2038 Phase 2²⁹ or Phase 3¹⁰⁴ trials. In fact, in the Phase 2 trial participants were stabilized inpatient on 30 mg of morphine four times daily by mouth and then inducted onto 24 or 32 mg weekly CAM2038 15 hours after the last morphine dose (as long as the COWS was ≥ 8) without precipitated withdrawal. In addition, the authors of the Phase 2 trial reported: *“Owing to a protocol error that may have been somewhat serendipitous, some participants received their first CAM2038 injection with little to no evidence of withdrawal (COWS score < 8); none experienced precipitated withdrawal”*.²⁹ Second, the slower time to onset of C_{max} with the injection (24 hours) versus sublingual buprenorphine/naloxone (2.5 hours) theoretically should decrease the risk of precipitated withdrawal from BUP-XR compared to BUP-SL. Thus, site protocols used for induction on BUP-SL should mitigate risk of precipitated withdrawal from CAM2038. Third, sites will be instructed to only administer the injection when the participants are in opioid withdrawal if they are not already taking BUP-SL.

If precipitated withdrawal does occur after CAM2038 administration, no additional buprenorphine should be given since the levels of buprenorphine will be steadily increasing until they reach a maximum concentration at 24 hours post-administration. Symptomatic non-opioid treatments may be offered as needed to treat withdrawal signs and symptoms as clinically indicated at each site. For example, ondansetron may be administered for nausea and vomiting, acetaminophen for aches and pain, hydroxyzine for anxiety/restlessness, loperamide for loose stool/diarrhea and cyclobenzaprine for muscle cramping. Sites may determine which non-opioid as-needed medications they want to administer, and these medications will be captured as concomitant medications. Reassurance and monitoring should continue until the withdrawal dissipates. Each site should clinically determine whether the withdrawal is severe enough to warrant: 1) a longer visit to allow time for reassessment, fetal monitoring (to assure continued viability of fetus) and

reassurance that the withdrawal is dissipating; 2) hospital admission (e.g., if participant's withdrawal is not subsiding and the withdrawal requires more intensive monitoring and treatment) – for example the participant is unable to stop vomiting and needs IV hydration, fetus needs more intensive monitoring, etc.; and/or 3) an unscheduled visit the following day in order to assure that the withdrawal has dissipated and the participant is stable. Each site must develop its own detailed SOP for handling precipitated withdrawal after CAM2038 administration, with the understanding that more buprenorphine should NOT be given within the 24-hour period after the injection was given. Sites may determine on a case-by-case basis if they want to give more buprenorphine after the 24-hour period after consultation with the site medically responsible investigator.

BUP-SL assignment: The BUP-SL induction procedures typically used by the site will be utilized. As each site already has clinical experience inducing patients onto BUP-SL, we will allow each site to develop its own SOP for handling precipitated withdrawal from BUP-SL and to determine if they want to give more buprenorphine in these cases.

All cases of precipitated withdrawal in either study arm will be considered adverse events. All medications given will be captured as concomitant medications. In the event that precipitated withdrawal leads to fetal monitoring, any action taken specifically as a result of the fetal monitoring will be documented.

9.4 Missed Doses

Study participants may miss doses for a number of reasons including incarceration. A participant who discontinues her medication, for any reason, and then returns to the clinic may be continued/re-induced on the medication to which she was randomized as long as it is clinically appropriate in the judgment of the prescribing clinician.

9.5 Clinical non-response

Participants with a sub-optimal clinical response to their medication, as determined by the prescribing clinician, may be referred for alternative treatment (e.g., methadone maintenance). Such participants will be encouraged to continue participating in the data collection aspects (e.g., research visits, urine collection, infant assessments) of CTN-0080.

9.6 Study Medication Management/Drug Accountability

Study sites are required to observe local, state, and federal regulations regarding receipt, custody, dispensing, and disposition of all study medications. Each site will maintain an adequate supply of unexpired study medications on site.

9.6.1 Storage

Study medication will be stored in compliance with federal, state, and local laws and institutional policy. Study medication will be stored in a secured location under the conditions specified by the investigator's brochure/package inserts and DEA requirements. Temperature logs should show a daily record of medication storage temperature.

9.6.2 Documentation

Upon receipt, the investigator, pharmacist, or authorized designee at each site is responsible for maintaining written inventory of the study medication obtained for the study. Appropriately qualified and trained study personnel maintain accurate and current accounting of all study medication by utilizing drug accountability records, which are made available for review by study monitors and other appropriate research personnel. Medication accountability records, including

perpetual inventory, will document the amount of study medication ordered, received, and medications administered to, dispensed to, and returned by an individual participant. As with all study documentation, medication accountability records must be maintained in accordance with Good Documentation Practices and must be attributable, legible, contemporaneous, original, accurate, and complete.

Accurate drug accountability records:

- Demonstrate that the study medication was dispensed according to the protocol;
- Document receipt of the study medication, date, lot #, expiration date, quantity, and dosage;
- Account for unopened, un-dispensed, unused, returned, waste, or broken medication;
- Dosing logs should record participant ID #, date dispensed, drug name, lot #, and amount dispensed;
- Indicate who dispensed or handled the study medication.

9.6.3 Used/Unused Medication

Study medication returned by a participant may not be re-issued for use. Unused study medication will be returned and logged into a perpetual inventory of study medication returned. Damaged, returned, expired, or unused study medication will be accounted for by the NIDA contract monitor and sent to the study central pharmacy which will arrange with a reverse distributor for eventual destruction. Other ancillary medications obtained for this study will be destroyed on site or sent for destruction per local institutional policies.

9.6.4 Lost Medication

At the discretion of the site study treatment team, very limited replacement of study medications will be permitted.

9.6.5 Medication Packaging

CAM2038 will be supplied in single use injection kits. The injection kit will be labeled for investigational use only.

Each individual package of sublingual medication, both the mono product and the buprenorphine/naloxone product, will contain the study drug information. The lot number, medication expiration date, and storage conditions, as well as manufacturer and distributor information, will be included on the medication. Each package will be labeled for investigational use only.

9.7 Concomitant Medications

Any medication (including prescription, over-the-counter, herbal supplements, and health store products) to be taken during the study ideally should be approved by the Medical Clinician. Participants who initiate treatment for OUD with methadone or extended-release naltrexone will need to be discontinued from study medication but can otherwise continue with study participation. Participants prescribed benzodiazepines or other CNS depressants should be cautioned to use them only as directed by their physician.

10.0 ANALYTICAL PLAN

10.1 Statistical Hypotheses for Primary Objective

10.1.1 Key Hypotheses

It is hypothesized that the BUP-XR, relative to the BUP-SL, group will: 1) not have greater illicit opioid use during pregnancy (primary, non-inferiority); 2) have lower infant NOWS severity (key secondary, superiority); and 3) not have greater postpartum illicit opioid use (key secondary, non-inferiority).

10.1.2 Secondary Hypotheses

It is also hypothesized that the BUP-XR, relative to the BUP-SL, group will have better:

1. Mother outcomes during pregnancy including significantly:
 - greater proportion of BUP adherent days during pregnancy
 - greater proportion of drug-negative urine samples
 - less opioid craving as assessed by the opioid craving scale
 - better prenatal care utilization as assessed with the APNCU index
2. Mother outcomes postpartum including significantly:
 - greater proportion of BUP adherent days
 - greater proportion of drug-negative urine samples
 - fewer opioid overdoses
 - less opioid craving as assessed by the opioid craving scale
3. Infant outcomes including significantly:
 - lower proportion of infants requiring opioid medication
 - shorter infant hospital length of stay
 - lower proportion of infants for whom adjunct medications are used to treat NOWS
 - lower proportion of infants with an ICD-10 code indicative of NOWS
 - larger head circumference
 - greater weight and length
 - greater gestational age at delivery
 - greater proportion of infants scoring above the ASQ-3 cut-off

10.2 Intent-to-Treat Participant Population

The intent-to-treat population is defined as the participants who are randomized to treatment for maternal outcomes, and their offspring for the infant outcomes.

10.3 Analysis Plan

Each primary and secondary efficacy outcome measure will be analyzed for the intent-to-treat (ITT) population.

The primary outcome will be assessed at a 2.5% significance level for non-inferiority, as recommended by the FDA.¹⁷⁶ If the test of BUP-XR being non-inferior to BUP-SL is statistically significant, then the superiority of the extended-release formulation over the sublingual formulation will be evaluated. There is no need to adjust for this second test if the initial test of non-inferiority is statistically significant. The infant key secondary outcome will be analyzed at the 5% significance level for superiority, and will be interpreted cautiously given the lack of adjustment for multiple testing and will use confidence intervals where possible. The other key secondary outcome (illicit opioid abstinence during postpartum) will be assessed at a 2.5% significance level for non-inferiority.

10.3.1 Non-Inferiority Margin

As noted in **section 4.0**, there is a dearth of research on the treatment of OUD in pregnant women and, thus, no data upon which to base the non-inferiority margin for CTN-0080 is available. However, the OPTIMA study, a current non-inferiority trial comparing BUP/NX-SL to methadone in non-pregnant participants, is utilizing a primary outcome similar to the CTN-0080 primary outcome (i.e., proportion of opioid-free UDSs collected at the time of the weekly medication check with missing UDSs imputed as positive).¹⁷⁷ The non-inferiority margin for the OPTIMA trial is 15%, which was selected based on a literature review and expert input.¹⁷⁷ Given the more vulnerable nature of the CTN-0080 patient population in which illicit opioid use impacts the health of not only the mother but also the infant, we originally selected the more conservative margin of 11% (i.e., $\Delta = 0.11$). However, research continues to suggest that OUD in pregnant and postpartum women is a critical issue in rural communities where access to MOUD is limited.¹⁷⁸ The most cited reason for not prescribing buprenorphine by both rural physicians¹⁷⁹ and nurse practitioners/ physician assistants¹⁸⁰ with a buprenorphine waiver is concern about diversion/misuse. Since this concern would be eliminated by BUP-XR and, hence, BUP-XR has the potential to substantially increase MOUD access for pregnant/postpartum women, it was determined that the 11% margin was overly conservative. Hence, the margin was changed to 15% (i.e., $\Delta = 0.15$), which takes into account both the greater vulnerability of pregnant women with OUD and the potential of BUP-XR to substantially increase MOUD access, neither of which is present in the OPTIMA trial and which balance out to utilizing the 15% OPTIMA non-inferiority margin. As outlined in section 10.4 (Sample Size Analysis), the change in margin decreased the number of participants needed for an adequately-powered primary outcome to 176. As noted in **section 6.2**, the target sample size is approximately 200 participants, which would provide more power for secondary analyses, but the primary analysis will be adequately powered with 176 participants. This decrease in required sample size increases the feasibility of the MOMs trial, which was initiated at the start of the COVID-19 epidemic, which, in turn, adversely impacted the randomization rate at all of the study sites. Note that this non-inferiority margin will be used for both the primary outcome, as well as the key secondary outcome of postpartum illicit opioid abstinence.

10.3.2 Key Outcomes

Illicit opioid abstinence during pregnancy. As noted previously, this primary outcome measure is based on urine testing. It is operationalized as the percent of expected UDSs that are negative for illicit opioids. One UDS is expected at the time of each weekly Medication Check Visit between randomization and delivery – any missing UDS is imputed as positive (see **section 10.3.5**). The number of expected UDSs will be dependent on the length of time between randomization and

delivery, thus we operationalize this primary outcome measure as the *percent* of expected UDSs that are illicit opioid-negative.

The non-inferiority design results in the following hypotheses where μ_A is the mean in arm A and Δ the non-inferiority margin:

$$H_0(BUP - XR \text{ is inferior to BUP - SL}): \mu_{XR} - \mu_{SL} \leq -\Delta$$

$$H_1(BUP - XR \text{ is non - inferior to BUP - SL}): \mu_{XR} - \mu_{SL} > -\Delta .$$

To evaluate non-inferiority at the 2.5% significance level, the two-sided 95% confidence interval for the treatment effect, $\mu_{XR} - \mu_{SL}$, will be calculated using a mixed effects model where treatment arm is a fixed effect and the three randomization factors (site, EGA and BUP-SL status at randomization) are random effects. If the lower limit of the confidence interval is greater than -0.15 (i.e., $\Delta=0.15$), we will reject the null hypothesis and conclude non-inferiority of BUP-XR to BUP-SL. Only if the null hypothesis is rejected will superiority of BUP-XR to BUP-SL be considered. This will involve examining the two-sided 95% confidence interval for the treatment effect, $\mu_{XR} - \mu_{SL}$. If the lower limit is above zero, then we can conclude that the extended-release formulation is superior to the sublingual formulation. If this order of testing is followed, then there is no need to adjust for multiplicity.^{176, 181} Additional covariates for secondary modeling are described in **section 7.4**. In the event that the distributional assumptions involved in the mixed effects model are not met, which is likely, alternative non-parametric methods will be considered for this modelling such as quantile regression.

Total days of opioid treatment. Total days of infant opioid treatment will be obtained from the medical record. There are extensive covariates to be included in modelling for the infant outcomes (**Table 2**) at the mother-, infant-, and delivery-hospital-level. Explanation for these covariates is provided in **section 7.4**. Since this outcome measure is a count variable and there are covariates requiring adjustment, modelling will utilize Poisson regression. The treatment effect will be measured by the regression coefficient for treatment assignment in the model ($H_0: \beta=0$; $H_1: \beta \neq 0$).

Illicit opioid abstinence during postpartum. The analytic approach will follow the one outlined above for testing the primary outcome.

10.3.3 Secondary Outcomes

For binary secondary outcomes, such as the proportion of infants requiring opioid medication, and the proportion with an ICD-10 code indicating NOWS, logistic regression or Pearson's χ^2 test of association or another appropriate method will be used to assess the relationship with treatment assignment. Continuous outcomes, such as medication adherence, opioid craving during pregnancy and infant weight at delivery, will be modelled using ANOVA or an appropriate alternative (e.g., quantile regression) to evaluate the effectiveness of BUP-XR. Lastly, the number of opioid overdoses can be modeled as a count variable with possibly zero-inflation, thus a method such as Poisson or Zero-Inflated Poisson regression can be implemented.

10.3.4 Safety Analyses

10.3.4.1 Adverse Events

For mothers, adverse events (AEs), including serious adverse events (SAEs), will be summarized by system organ class and preferred term using MedDRA (The Medical Dictionary for Regulatory Activities). Adverse events will be presented as the number and proportion of participants experiencing at least one incidence of each event and will be presented overall and by treatment

group. Listings of serious adverse events will be provided, sorted by treatment, system organ class, and preferred term. Detail in these listings will include severity, relationship to study drug, and outcome. The number of participants experiencing each type of AE and SAE may be compared between treatment arms using either Fisher's Exact test or Pearson's χ^2 test, as appropriate.

For infants, events will be summarized in a similar way, however, infant death, congenital anomalies in all infants and other infant SAEs in breastfed infants are reportable.

10.3.4.2 *The Hospital Anxiety and Depression Scale (HADS)*

Depression and anxiety scores, as measured by the HADS, will be summarized using descriptive statistics over time by treatment arm. Repeated measures mixed models may be used to compare the treatment groups on the depression and anxiety symptoms from screening/baseline through 12 months postpartum.

10.3.4.3 *Fetus/Delivery-Related Outcomes*

Fetus/delivery-related outcomes will be summarized by treatment arm. Listings may be provided for fetus- or delivery-related outcomes of particular concern and will be broken down by treatment arm.

10.3.4.4 *Birth/Neonatal Outcomes*

Outcomes related to the birth and/or neonate, such as head circumference or the need for resuscitation, will be summarized by treatment arm and listings may be provided for adverse outcomes, as needed.

10.3.5 Missing Data

Key outcomes. Illicit opioid use during pregnancy (primary outcome) and postpartum (key secondary) are based on UDS; missing UDSs will be imputed as illicit opioid-positive. The number of expected UDSs for each participant during pregnancy will depend on the length of time between randomization and delivery. UDSs are expected at the time of each weekly Medication Check Visit, thus a mother who is on study, for example, for 60 days will be expected to have had 8 UDSs. The final key secondary outcome measure, infant days of opioid treatment, is based on medical records and thus missing data should be minimal. It is possible, albeit rare, given the site selection criteria and the plan for study staff to obtain medical releases for multiple facilities, that a mother may deliver at a hospital for which medical records could not be obtained, and in this case the infant days of opioid treatment will be imputed as the worst value observed (i.e., greatest number of days). Another possible source of missing data will be if the pregnancy does not result in live birth. In this very rare case, the infant days of opioid treatment will also be imputed as the greatest number of days amongst the observed infants.

Different imputation methods, such as those loosening the missing at random assumption, may be considered to measure the sensitivity of the study results to these methods of handling missing data. Sensitivity analyses relating to the impact of the COVID-19 pandemic may be considered as well.

10.4 Sample Size Analysis

10.4.1 Parameter Selection for Calculations

The power analyses required BUP-SL group estimates for the mean and variance of the percent of UDS that are illicit opioid-negative during pregnancy. The mean selected for the sample size simulations was based on a study by Fischer and colleagues¹⁸² which found that the median percentage of urine samples negative for illicit opioids during the entire course of pregnancy was 65% for BUP-SL participants.

10.4.2 Results

Approach. Given a non-inferiority margin of 0.15, the objective of the sample size simulations was to determine whether there would be sufficient power (i.e., $\geq 80\%$) to detect that margin with a sample size of 200 participants under different assumptions regarding the impact of the three factors used in randomization. There must be sufficient power if the primary analytic model includes the randomization factors as covariates even if they are not associated with outcome. All simulated data assumed 1:1 random allocation between the treatment arms and thus one half in the BUP-XR arm and one half in the BUP-SL arm.

A simulation study was conducted to assess the power. The details of the simulation will be included in the standalone Statistical Analysis Plan. The mean in the BUP-SL arm was assumed to be 0.65 (**section 10.4.1**), and the mean in the BUP-XR arm was assumed to be 0.50 under the null, which corresponds to the specific non-inferiority margin of 0.15, and 0.65 under the alternative. The variance in both arms was fixed at 0.11, with contributions coming from the three random effects capturing randomization strata/factors and additional random error.

Results. The results of the simulations evaluating the power and type I error for the conservative case where all variance is due to random error and none due to the three random effects is given in **Table 8**. Even if the randomization factors are not associated with the outcome, there will still be *at least* 80% power to detect a 0.15 non-inferiority margin with a 2.5% significance level and a sample size of 200. Note that there is at least 80% power with a slightly lower sample size of 176 as well, meaning that the primary outcome is adequately powered with a sample size of 176.

Table 8. Power for a non-inferiority margin of 15% and a significance level of 2.5%.

Proportion of Variance due to Random Error	Mean in BUP-XR Arm	Power (%)	
		N = 176	N = 200
100%	0.50	2.7%	2.4%
	0.65	84.9%	89.0%

10.5 Descriptive Statistics

Summaries of the characteristics of the participant population in both treatment arms at screening/baseline will be prepared for the intent-to-treat participants. A summary will be prepared to show dropouts/retention over time in each treatment group. The number of missing observations will be compared between treatments.

10.6 Interim Analyses

An interim check of the parameters contributing to the initial power calculations for the BUP-SL group (mean and standard deviation for the percent opioid-negative UDS during pregnancy) will be conducted by the centralized independent DSC. The required sample size to achieve at least

80% power with a margin of 0.15 and a 2.5% type I error rate will be re-calculated. The Data and Safety Monitoring Board (DSMB) will assess whether to continue the trial with or without modification. This interim re-estimation will be implemented since these parameters are being estimated from limited repeated measures data and involve several key assumptions that impact the detectable effect size. The analysis will be conducted when approximately 100 participants (about 50 in the sublingual arm) have been randomized and have primary outcome data available (i.e., completed pregnancy portion of the active treatment phase).

A DSMB will monitor the progress of the present trial. An interim analysis could be performed to assess efficacy, futility, or safety if requested by the DSMB or NIDA. Trial monitoring guidelines for early stopping based on overwhelming benefit might be based on the Lan-DeMets approach to group sequential testing¹⁸³ with an O'Brien-Fleming-type boundary.¹⁸⁴ Such an approach does not require the number of interim looks, if any, to be specific *a priori*. The monitoring guidance for early stopping for lack of benefit or for futility might be based upon an approach of conditional probability.¹⁸⁵ Additional safety interim looks could be performed (without formal testing being performed) at the DSMB's or NIDA's request.

10.7 Minority/Sex Analyses

In accordance with National Institutes of Health guidelines, modelling of the key outcomes will be completed to determine whether treatment response was significantly affected by participant minority/sex status using an interaction term between treatment arm and demographic factor being considered. The sex analyses will be completed for the infants. The minority analyses will be conducted for both the mother and infant outcomes.

10.8 Conceptual Model Analyses

Structural equation modeling¹⁸⁶ will be used to test the conceptual models described in **section 4.4**.

10.9 Health Economic Analytic Plan

A tertiary objective of MOMs is to conduct a health economic analysis comparing the costs and benefits of BUP-XR and BUP-SL; this section describes the analyses to be conducted.

10.9.1 Overview

The economic analyses will be conducted using well-established guidelines,^{132, 187, 188} from the perspective of the healthcare sector, as per the recommendation of the Second Panel on Cost Effectiveness in Health and Medicine.¹³² The healthcare sector perspective includes all formal (medical) costs incurred by the system on behalf of participants in each arm, and their infants. First, we will determine and value the resources required to start up and manage each treatment strategy on a continuing basis, by site. Next, we will evaluate whether BUP-XR for OUD treatment of pregnant women is associated with more primary, obstetrical, and behavioral healthcare services but fewer emergency and inpatient services; enhanced participant wellbeing; and economic viability, compared to BUP-SL.

The data sources defined in **section 7.5** will be used to capture all available healthcare service utilization for participants in both arms over the entire study period (i.e., pregnancy-delivery and postpartum). The resource costing method will be used to estimate participant-level costs. This method is a powerful tool in a clinical trial environment; it involves determining a price weight for each resource unit consumed and multiplying price weights by units of service.^{132, 188, 189} Unit costs will be derived from sources reflecting national real-world costs faced by the healthcare sector.

The U.S. Department of Veterans Affairs Federal Supply Schedule will be used to value all medications, as per the current guidelines.¹³² Medicare fee-for-service payments will be used to value other healthcare resources, as these payments are designed to reimburse providers for the resources that would be used to treat a typical patient with a given condition and are adjusted for relevant factors that are unique to the patient or provider,¹⁹⁰ as opposed to also including a component for profit and risk adjustment.¹³²

To begin, we will conduct bivariate analyses (t-tests for continuous measures and chi-square tests for categorical measures; nonparametric tests will be used for measures that fail to satisfy the assumptions of parametric tests) to test for baseline differences between arms for factors relevant to the economic analysis that may not have been considered in the randomization process (e.g., HRQoL). All data will be analyzed under an intent-to-treat principle. We will model the person period monthly during the pregnancy and delivery phase, and every other month during the 12-month postpartum phase. All analyses will be conducted using a multivariable Generalized Linear Mixed Model (GLMM). The GLMM is an extension of the GLM that allows for the inclusion of random effects. The multivariable aspect of the model is crucial as it allows for the control of factors that are unbalanced between arms because they were not accounted for in the randomization process or may have become unbalanced due to loss to follow-up. The GLMM allows one to choose the most appropriate mean and variance functions according to the fit of the data, and uses all available data for each participant, regardless of whether or not it is complete, making it an ideal statistical procedure for intent-to-treat approaches.¹⁸⁸ Given the differences in mechanisms to generate data, separate multivariable GLMMs will be estimated to predict the mean value for each resource and outcome, at each time period, by study arm. The statistical method of recycled predictions will be used to obtain the final predicted mean values, which will be summed and tested over the pregnancy and delivery phase, and over the entire study period.¹⁸⁸ To account for sampling uncertainty in point estimates, the p-values and standard errors will be estimated using nonparametric bootstrapping techniques within the multivariable framework. All monetary values will be adjusted for inflation. Follow-up measurements obtained beyond 12 months of baseline will be discounted for time preference using the recommended rate of 3%.^{132, 188} Our team has extensive experience applying these methods.¹³⁸⁻¹⁴¹

10.9.2 Intervention Costs

The resources used to implement and administer each treatment strategy, by site, will be estimated using a combination of macro- and micro-costing analyses. To the extent possible, costs will be estimated using a macro-costing (“top down”) approach based on information obtained from the PAASA (see **section 7.4**). These data may be supplemented with data collected during semi-structured interviews with site clinical leaders, that will allow us to assign individual resources (time and materials) used to deliver the intervention using micro-costing (“bottom up”) techniques.

10.9.3 Healthcare Service Utilization

The analytic methods described in **section 10.9.1** will be used to test for differences in utilization of healthcare services, as well as their associated costs, at baseline and over time.

10.9.4 QALYs

We will test for differences in QALYs gained between study arms over the pregnancy and delivery phase, and over the entire study period. A multivariable GLMM regression will be used to estimate the predicted health utility index value for each arm at each time period. The predicted health utility index value will be used to weight the amount of time associated with the arm’s typical health

state, and mean QALYs gained over time for each arm will be estimated using the area under the curve methodology.^{132, 188, 191}

10.9.5 ICERs and Cost-Effectiveness

The costs calculated in **sections 10.9.2** and **10.9.3** will be combined and the difference between the two arms will be calculated to form the numerator of the ICER (see **section 7.5**). Four ICERs will be calculated, since we are evaluating two measures of effectiveness (QALYs; Abstinent Years) over two time periods of interest (pregnancy and delivery; entire study period). ICER confidence intervals will be estimated using nonparametric bootstrapping techniques within the multivariable framework. Parametric methods based on parameters obtained from bootstrapping will be used to estimate acceptability curves, which will illustrate the probability that the BUP-XR is a good value relative to BUP-SL for different willingness-to-pay thresholds (i.e., cost-per-QALY and cost-per-Abstinent-Year). ICERs will be calculated and acceptability curves will be constructed regardless of the statistical significance for individual cost and effectiveness differences, as the power to detect a difference in costs and effects jointly exceeds the power to do so individually.¹⁸⁸

10.9.6 Missing Health Economic Data

To help address censored data we will model the monthly person period and estimate all multivariable regressions using the GLMM, which uses all available data for each participant, regardless of whether the data are complete.¹⁸⁸ In all cases we will diagnose the mechanism of censoring or missingness (i.e., missing completely at random (MCAR), missing at random (MAR), or missing not at random (MNAR)). Logistic regression models predicting missingness, based on participant characteristics and prior measures, will be used to determine whether the data are MCAR and thus ignorable.¹⁹² If not, we will address the missingness using the most appropriate method.¹⁸⁸ We will also conduct extensive sensitivity analyses, including MNAR approaches, to examine the robustness of our outcomes under varying assumptions.¹⁹³

10.9.7 Sensitivity Analyses

Sensitivity analyses will be performed to account for uncertain precision in assumptions and parameter estimates applied in the analyses.¹³² For example, we will test the robustness of the results as they pertain to variations in the unit cost estimates, and in the cost of implementing and managing each treatment strategy. Also, values estimated using the more robust and efficient GLMM regression will be compared to those estimated using the more transparent ordinary least squares regression, as well as to the unadjusted mean values.

10.10 Neurodevelopmental Outcomes Analysis

A quaternary objective is to evaluate the impact of BUP-XR, relative to BUP-SL, on neurodevelopment when the infant/child is approximately 12 and 24 months of age. The main outcome is the score on the cognitive subscale of the Bayley™-4 at 24 months of age. The primary method of analysis will be a t-test. For modelling purposes, a mixed model may be used to account for the repeated measures nature of the data and potential covariates, or an alternative approach that allows for multiple outcome measures per infant/child and construction of a contrast to test the treatment effect at 24 months of age.

10.11 Post-hoc Analyses

In addition to the analyses described above, a number of post-hoc analyses will be completed. Some examples of possible analyses include an exploration of participant screening/baseline

variables that are predictive of treatment outcome, and site characteristics associated with treatment outcome.

11.0 REGULATORY COMPLIANCE, REPORTING, AND MONITORING

11.1 Regulatory Compliance

Written approval for the study protocol, consent forms, other supporting documents, and any advertising for participant recruitment will be provided to the sites by the Institutional Review Board (IRB) of record prior to participation in the study. Any amendments to the protocol or consent materials must be approved by the IRB of record before they are implemented. Unanticipated problems involving risk to study participants will be promptly reported to and reviewed by the IRB of record, according to its usual procedures. Annual progress reports and local SAE reports will be submitted to the IRB, according to its usual procedures.

The study will be registered and updated as needed in www.ClinicalTrials.gov.

11.2 Statement of Compliance

This study will be conducted in accordance with the current version of the protocol, in full conformity with the ethical principles outlined in the Declaration of Helsinki, the Regulations for the Protection of Human Subjects codified in the International Council for Harmonisation GCP Guidelines, and all other applicable regulatory requirements. An Operations Manual will be provided as a reference guide and study quality assurance tool.

11.3 Institutional Review Board Approval

Per NOT-OD-16-094, the University of Cincinnati IRB (UC IRB) will be the IRB of record for the protocol and will provide study oversight in accordance with 45 CFR 46. Participating institutions will be asked to agree to rely on the UC IRB and will enter into reliance/authorization agreements for Protocol CTN-0080, as needed. The UC IRB will follow written procedures for reporting its findings and actions to appropriate officials at each participating institution.

Prior to initiating the study, the lead team will ensure that the local IRB at each site involved has entered into a reliance/authorization agreement with the IRB of record (UC IRB) and that written IRB approval has been secured from the IRB of record for each site involved. If changes to the study protocol become necessary, protocol amendments will be submitted in writing for approval by the IRB of record prior to implementation. In addition, the IRB of record will approve all consent forms, recruitment materials, any materials given to the participant, and any changes made to these documents throughout study implementation. For changes to the consent form, a decision will be made regarding whether previously consented participants need to be re-consented. IRB continuing review will be performed annually, or at a greater frequency contingent upon the complexity and risk of the study. Each site principal investigator (PI) is responsible for maintaining copies of all current IRB approval notices, IRB-approved consent documents, and approval for all protocol modifications. These materials must be received by the investigator prior to the initiation of research activities at the site and must be available at any time for audit.

11.4 Regulatory Files

Essential documents are those documents which individually and collectively permit evaluation of the conduct of a trial and the quality of the data produced. These documents serve to demonstrate the compliance of the investigator, sponsor, and monitor with the standards of GCP and with all applicable regulatory requirements. The regulatory files should contain all essential documents, other required regulatory documents, study-specific documents, and all important communications. Regulatory files will be checked at each participating site for compliance prior to study initiation, throughout the study, as well as at study closure. The Clinical Coordinating

Center (CCC) will collaborate with the sites to monitor whether all sponsor-required regulatory documents have been uploaded into the Veeva Vault eTMF.

11.5 Research Advisory Panel of California (California sites only)

Prior to initiating the study, the sponsor or designee will obtain written approval from the Research Advisory Panel of California (RAP-C). Any planned research project to be conducted in California requiring the use of a Schedule I or Schedule II Controlled Substance as its main study medication, as well as research for the treatment of controlled substance addiction or abuse utilizing any drug, scheduled or not (SAT), must be submitted to RAP-C for review and approval prior to study start-up. Study approval is based on review of the study protocol, consent form, and other pertinent study documents. Yearly reports will be provided to the RAP-C by the sponsor or designee in order to obtain continuing study approval. Protocol amendments will also be submitted, and it is required that the Panel be notified of any significant study medication related adverse events that may emerge during conduct of the study at the California sites only.

11.6 Informed Consent

The informed consent form is a means of providing information regarding the trial to a prospective participant and allows for an informed decision about participation in the study. Informed consent continues throughout the individual's study participation. Each study site must have the study informed consent approved by the UC IRB. Prior to initial submission to the IRB and with each subsequent consent revision, the consent form(s) must be sent to the Clinical Coordinating Center and the Lead Node to confirm that each consent form contains the required elements of informed consent as delineated in 21 CFR 50.25(a) and CFR 46.116(b), pertinent additional elements detailed in 21 CFR 50.25(b) and 45 CFR 46.116(c), and any applicable Center for Clinical Trials Network (CCTN) requirements. Every study participant is required to sign a valid, IRB-approved, current version of the study informed consent form prior to the initiation of any study related procedures. The site must maintain the original signed informed consent for every participant in a locked, secure location that is in compliance with all applicable IRB and institutional policies and that is accessible for quality assurance and study monitor review. Every study participant should be given a copy of the signed consent form. Additionally, participants at any California sites will be provided with a copy of the California Research Participant's Bill of Rights.

Prior to signing the informed consent form, research staff who are knowledgeable about the study will explain the study to the potential participant and provide the participant with a copy of the consent to read during the consent (or re-consent) process and to keep for reference. All participants will receive a verbal explanation in terms suited to their comprehension of the purposes, procedures, and potential risks of the study and their rights as research participants. Extensive discussion of risks and possible benefits will be provided to the participants. Participants will have the opportunity to carefully review the written consent form and ask questions prior to signing. The participants should have the opportunity to discuss the study with their family and close friends or think about it prior to agreeing to participate. If the participant is interested in participating in the study, a researcher who is authorized by the PI to obtain informed consent and approved by the UC IRB, will review each section of the informed consent form in detail, answer any of the participant's questions, and determine if the participant comprehends the information provided by administering the comprehension tool. The participant, or participant's legally authorized representative, will consent by signing and dating the consent documents. The person obtaining consent will also sign and date the consent document. The consent must be properly executed and complete to be valid. It is strongly recommended that another research staff member review the consent after it is signed to ensure that the consent is properly executed and complete.

Staff members delegated by the PI to obtain informed consent must be listed on the Delegation of Responsibility and Staff Signature Log. All persons obtaining consent must have completed appropriate GCP and Human Subjects Protection training, as mandated by NIDA standard operating procedures.

The informed consent form must be updated or revised whenever important new safety information is available, or whenever the protocol is amended in a way that may affect a participant's participation in the trial. The rights and welfare of the participants will be protected by emphasizing to them that the quality of their medical care will not be adversely affected if they decline to participate in this study. The participant will be informed that their participation is voluntary, and they may withdraw from the study at any time, for any reason, without penalty. Individuals who refuse to participate or who withdraw from the study will be treated without prejudice.

For this study, there will be up to four written consents: One for the mother and her as-yet-unborn child to participate in the primary study, one for the mother and her as-yet-unborn child to participate in the CMA sub-study, and one for the caregiver and infant to participate in the INO sub-study; the INO sub-study consent must be co-signed by the infant's Legally Authorized Representative (LAR) in the event that the birth mother no longer has legal authority for the infant. A fourth consent, to be signed by the LAR for the infant, will be used in the event that the birth mother no longer has legal authority for the infant during the postpartum phase of the primary study. The study will seek a waiver of consent for the infant's caregiver to provide information about the infant's development and living environment should the mother lose or surrender custody of the child prior to the end of her participation in the study.

11.7 Participant and Data Confidentiality

Confidentiality will be maintained in accordance with all applicable federal regulations and/or state/Commonwealth law and regulations. By signing the protocol signature page, the investigator affirms that information furnished to the investigator by NIDA will be maintained in confidence and such information will be divulged to the IRB of record; affiliated institution; and employees only under an appropriate understanding of confidentiality with such board or committee, affiliated institution, and employees.

This study will be covered by a federal Certificate of Confidentiality (CoC), which protects identifiable research information from forced disclosure. This protects participants against disclosure of sensitive information (e.g., drug use). The CoC allows the investigator and others who have access to research records to permanently refuse to disclose identifying information on research participation in any civil, criminal, administrative, legislative, or other proceeding, whether at the federal, state, or local level, excepting certain circumstances.

By protecting researchers and institutions from being compelled to disclose information that would identify research participants, the CoC helps achieve the research objectives and promote participation in studies by helping assure confidentiality and privacy to participants. Participant records will be held confidential by the use of study codes for identifying participants on CRFs, secure storage of any documents that have participant identifiers, secure transport of study documents while performing study visits at any off-site location, and secure computing procedures for entering and transferring electronic data.

11.7.1 Health Insurance Portability and Accountability Act (HIPAA)

Study sites may be required by their institutions to obtain authorization from participants for use of protected health information. Releases of participant identifying information that are permitted

by the HIPAA regulations, but which are prohibited by other applicable federal regulations and/or state/Commonwealth law and regulation, are prohibited. Sites will be responsible for communicating with the IRB of record and obtaining the appropriate approvals or waivers to be in regulatory compliance.

11.8 Investigator Assurances

Each site must file (or have previously filed) a Federalwide Assurance with the Department of Health and Human Services (HHS) Office for Human Research Protection setting forth the commitment of the organization to establish appropriate policies and procedures for the protection of human research subjects in alignment with 45 CFR 46, Subpart A, with documentation sent to NIDA or its designee. Research covered by these regulations cannot proceed in any manner prior to NIDA receipt of certification that the research has been reviewed and approved by the IRB provided for in the assurance (45 CFR 46.103). Prior to initiating the study, the PI at each study site will sign a protocol signature page, providing assurances that the study will be performed according to the standards stipulated therein.

11.8.1 Financial Disclosure/Conflict of Interest

All investigators will comply with the requirements of 42 CFR Part 50, Subpart F to ensure that the design, conduct, and reporting of the research will not be biased by any conflicting financial interest. Everyone with decision-making responsibilities regarding the protocol will confirm to the sponsor annually that they have met their institutional financial disclosure requirements.

11.8.2 DEA Registration

All Drug Enforcement Agency (DEA) requirements must be met, including registration, inspection if required, and certification, as applicable. In order to receive shipments of study drug, sites must have a DEA registration (facility research registration or a practitioner registration) that has the address where study drug will be shipped on the registration. Additionally, dispensing any controlled substance requires a DEA registration unless exempt by federal or state law or pursuant to CFR Sections 1301.22-1301.26. Sites will follow local DEA guidance regarding the movement of controlled study medications between the registered site and off-site study visit locations.

11.8.3 Investigational New Drug (IND) Requirements

An IND application has been accepted by the FDA for this study (IND# 140724). Any subsequent amendments to this clinical trial submitted to the FDA for review will reflect awareness of and compliance with U.S. Code of Federal Regulations 21 CFR 312 and its subparts, as well as the International Council on Harmonisation GCP Guidelines (ICH E6 R2). This IND study will also be conducted in accordance with all applicable FDA regulations and will comply with all applicable laws and regulations at clinical research sites.

11.9 Quality Assurance Monitoring

In accordance with federal regulations, the study sponsor is responsible for ensuring proper monitoring of a clinical trial and ensuring that the trial is conducted in accordance with the protocol. Qualified monitors will oversee aspects of site conformity to make certain the site staff is operating within the confines of the protocol, and in accordance with GCP. This includes but is not limited to protocol compliance, documentation auditing, monitoring of drug disposition, and evaluating whether the informed consent process is being correctly followed and documented. Non-

conformity with protocol and federal regulations can be reported as a protocol deviation and submitted to the study sponsor and study IRB for further review.

Investigators will host periodic visits by NIDA contract monitors who will ensure all study procedures are conducted, site and study SOPs are followed, and that study data are generated, documented and reported in compliance with the protocol, GCP, and applicable regulations. These monitors will audit, at mutually agreed upon times, regulatory documents, CRFs, and corresponding source documents for each participant. Monitors will have the opportunity and ability to review any study-associated document or file.

NIDA-contracted monitors will assess whether submitted data are accurate and in agreement with source documentation and will also review regulatory/essential documents such as correspondence with the IRB. Areas of particular concern will be participant informed consent forms, protocol adherence, reported safety events and corresponding assessments, and PI oversight and involvement in the trial. Reports will be prepared following the visit and forwarded to the site PI, the Lead Investigator (LI), and NIDA Center for Clinical Trials Network (CCTN).

Qualified node personnel (Node Protocol Managers and/or Quality Assurance (QA) monitors) or other designated party(ies) will provide site management for each site during the trial. Node QA personnel or other designated party(ies) will audit source documentation, including informed consent forms and HIPAA forms. This will take place as specified by the local protocol team, node PI or lead team and will occur as often as needed to help prevent, detect, and correct problems at the study sites. Node QA personnel will verify that study procedures are properly followed and that site staffs are trained and able to conduct the protocol appropriately. If the node staff's review of study documentation indicates that additional training of study personnel is needed, node staff will undertake or arrange for that training. Details of the contract, node QA and data monitoring are found in the study QA monitoring plan.

11.10 Prisoner Certification

As per 45 CFR 46 Subpart C, there are additional protections pertaining to prisoners as study participants. A prisoner is defined as any individual involuntarily confined or detained in a penal institution. The term is intended to encompass individuals sentenced to such an institution under a criminal or civil statute, individuals detained in other facilities by virtue of statutes or commitment procedures which provide alternatives to criminal prosecution or incarceration in a penal institution, and individuals detained pending arraignment, trial, or sentencing. In order to meet these additional protections, the study team will obtain certification from the Office for Human Research Protections (OHRP) to follow-up with participants who become prisoners during the course of the study, as necessary. For individuals who are, or become during the course of their participation, prisoners, study participation will have no effect on the participant's criminal case, release or parole from jail or prison, or probation case.

11.11 Protections for Pregnant Women, Fetuses, and Neonates

As per 45 CFR 46 Subpart B, there are additional protections pertaining to pregnant women, fetuses, and neonates involved in research. Pregnancy encompasses the period of time from implantation until delivery. Fetus is defined as the product of conception from implantation until delivery. In order to meet these additional protections, study staff will abide by conditions outlined in 45 CFR 46.201-206. Potential participants will be fully informed regarding the reasonably foreseeable impact of the research on the fetus or neonate.

11.12 Records Retention and Requirements

Research records for all study participants (e.g., CRFs, source documents, signed consent forms, audio and video recordings, and regulatory files) are to be maintained by the investigator in a secure location for a minimum of 3 years after the study is completed and closed. These records are also to be maintained in compliance with IRB, state and federal requirements, whichever is longest. The sponsor and LI must be notified in writing and acknowledgment must be received by the site prior to the destruction or relocation of research records.

11.13 Reporting to Sponsor

The site PIs agree to submit accurate, complete, legible and timely reports to the Sponsor, as required. These include, but are not limited to, reports of any changes that significantly affect the conduct or outcome of the trial or increase risk to study participants. Safety reporting will occur as described in **section 11.17** and the **safety appendix**. At the completion of the trial, the LI will provide a final report to the Sponsor.

11.14 Audits

The Sponsor has an obligation to ensure that this trial is conducted according to GCP guidelines and may perform quality assurance audits for protocol compliance. The LI and authorized staff from the Ohio Valley Node; the National Institute on Drug Abuse Clinical Trials Network (NIDA CTN, the study sponsor); NIDA's contracted agents, monitors or auditors; monitors from the site's local Node, and other agencies such as the HHS, the OHRP and the IRB of record or the FDA may inspect research records for verification of data, compliance with federal guidelines on human participant research, and to assess participant safety.

11.15 Study Documentation

Each participating site will maintain appropriate study documentation (including medical and research records) for this trial, in compliance with ICH E6 and regulatory and institutional requirements for the protection of confidentiality of participants. Study documentation includes all data-related forms, workbooks, source documents, monitoring logs and appointment schedules; sponsor-investigator correspondence, and signed protocol and amendments; IRB correspondence; and approved consent form and signed participant consent forms. As part of participating in a NIDA-sponsored study, each site will permit authorized representatives from NIDA, NIDA's contracted agents, monitors, or auditors, monitors from the site's local Node, and regulatory agencies to examine (and when permitted by law, to copy) clinical records for the purposes of quality assurance reviews, audits, and evaluation of the study safety, progress, and data validity.

Source documents include all recordings of observations or notations of clinical activities and all reports and records necessary for the evaluation and reconstruction of the clinical research study. Whenever possible, the original recording of an observation should be retained as the source document; however, a photocopy is acceptable provided that it is a clear, legible, and exact duplication of the original document. If the original recording of an observation is the electronic record, that will be considered the source.

11.16 Protocol Deviations

Any departure from protocol-specified procedures and requirements will be classified as either a major or minor protocol deviation. The difference between a major and minor protocol deviation has to do with the seriousness of the event and the corrective action required. A minor protocol

deviation is considered an action (or inaction) that by itself is not likely to affect the scientific soundness of the investigation or seriously affect the safety, rights, or welfare of a study participant. Major protocol deviations are departures that may compromise the participant safety, participant rights, inclusion/exclusion criteria, or the integrity of study data and could be cause for corrective actions if not rectified or prevented from re-occurrence. Sites will be responsible for developing corrective action plans for both major and minor deviations as appropriate. Those corrective action plans may be reviewed/approved by the Lead Node and the CCC with overall approval by the IRB of record. All protocol deviations will be monitored at each site for (1) significance, (2) frequency, and (3) impact on the study objectives, to ensure that site performance does not compromise the integrity of the trial. Departures from SOPs not detailed within the protocol will not be considered to be protocol deviations.

Protocol deviations will be recorded in the Electronic Data Capture (EDC) system via the Protocol Deviation CRF. The CCC, DSC, and the LI must be contacted immediately if an unqualified or ineligible participant is randomized into the study or if another major protocol deviation occurs.

Each site is responsible for reviewing the IRB of record's definition of a protocol deviation (minor deviation) or violation (major deviation) and understanding which events need to be reported to the IRB of record, and when reporting is to be done. Sites must recognize that the CTN and IRB definition of a reportable event may differ and act accordingly in following all reporting requirements for both entities.

11.17 Safety Monitoring

11.17.1 Data and Safety Monitoring Board (DSMB)

An independent CTN DSMB will examine accumulating data to assure protection of participants' safety while the study's scientific goals are being met. The CTN DSMB is responsible for conducting periodic reviews of accumulating safety and efficacy data. It will determine whether there is support for continuation of the trial, or evidence that study procedures should be changed, or if the trial should be halted, for reasons relating to the safety of the study participants, the efficacy of the treatment under study, or inadequate trial performance (e.g., poor recruitment).

11.17.2 Adverse Events (AEs)

The Site PI may appoint one or more Site Physicians/Medical Clinicians (MD, DO, or other medical clinician with DEA waiver or licensure to prescribe/dispense buprenorphine for treatment of opioid use disorder) for this study, who will review or provide consultation for each SAE, as needed. These reviews will include an assessment of the possible relatedness of the event to the study intervention or other study procedures. The Site Physicians/Medical Clinicians will also provide advice for decisions to exclude, refer, or withdraw participants as required. In addition, NIDA will assign a Medical Monitor to this protocol to independently review the safety data, present it to the DSMB for periodic review, and provide PIs a Safety Letter when necessary. The Medical Monitor will determine which safety events require expedited reporting to NIDA, the DSMB, pharmaceutical, and regulatory authorities. This will include events that are serious, related, and unexpected. The study staff will be trained to monitor for and report AEs and SAEs. Additionally, as applicable, sites will submit reporting of AEs/SAEs according to IRB requirements. Each of the sites has established practices for managing medical and psychiatric emergencies, and the study staff will continue to utilize these procedures. Treatment providers at each site will be responsible for monitoring participants for possible clinical deterioration or other problems, and for implementing appropriate courses of action.

Safety for this study will be monitored through specific study assessments and medical record abstraction in addition to more standard AE/SAE reporting.

The Hospital Anxiety and Depression Scale (HADS): The Hospital Anxiety and Depression Scale (HADS)¹¹⁷ will be used to assess for symptoms of depression and anxiety. Participants who score in the range for possible depression (total depression score of 8 or higher) or anxiety (total anxiety score of 8 or higher) will be assessed by a qualified clinician before leaving the visit as specified in the site clinical SOP. For visits held via telemedicine or at an external location, research staff will contact a qualified clinician via phone to coordinate an assessment via telemedicine as quickly as possible; ideally this assessment will occur while the staff and participant are together at the external location.

Prior/Concomitant Medications: All medications taken by the participant since the start of her pregnancy and during the active study will be documented on a Prior/Concomitant Medications assessment (see **Table 3**).

Fetal Outcomes: Gestational age at outcome, spontaneous abortions/miscarriages, stillbirth, pregnancy terminations and indications for termination.

Maternal Delivery Outcomes: Unplanned cesarean section, abnormal fetal presentation during delivery, medical complications at delivery, and analgesic receipt during labor and delivery, postpartum, and upon discharge.

Birth/Neonatal Outcomes: Birth/neonatal outcomes will be abstracted from the medical record. These outcomes include: head circumference, weight and length at birth, gestational age at delivery, and 1-minute and 5-minute Apgar (activity, pulse, grimace, appearance, respiration) scores. Other outcomes will include: major birth defects, stillbirth, neonatal death, and need for resuscitation. Adverse birth outcomes will be characterized, including (if preterm), the reason for preterm birth (e.g., fetal distress, etc.). Other adverse neonatal outcomes will be captured including respiratory distress symptoms, need for respiratory support in the neonatal unit, feeding problems (e.g., need for nasogastric tube), seizures, and other co-morbidities.

Injection Site Examination: Participants will be asked to immediately report any injection site reactions to study staff for evaluation, monitoring, and possible referral, as needed. For weekly injections, the site of the last BUP-XR injection will be examined at the weekly Medication Check Visits. For monthly injections, the BUP-XR injection site will be examined at the weekly Medication Check Visit following the visit during which the injection was given. Injection Site Examinations must be performed in-person. Injection site reactions will be documented on the Injection Site Reaction Reporting form.

Opioid Overdose Tracking: During the study, the participant will complete a self-report assessment about opioid overdose as outlined in **Table 3**. If a participant reports an overdose, research staff will refer her to the clinic staff who will follow up each case as specified in the site clinical SOP.

Infant Sedation: Infant sedation will be assessed via mother-report as outlined in **Table 3**. The infant sedation assessment will be completed by participants who are feeding their infants with breastmilk and/or formula and will assess for signs of infant sedation (e.g., not waking for feeding, difficulty breathing, etc.).

Bayley™-4. The Bayley™-4¹⁰² includes cognitive, language, fine motor, and gross motor subscales.

Child Behavior Checklist (CBCL). The CBCL¹⁷⁴ is administered to caregivers and includes items that describe behavioral, emotional, and social problems that characterize preschool children.

Events related to withdrawal symptoms will be captured on the SOWS-Gossop and will not be duplicate-reported on an AE form. However, precipitated withdrawal during study medication induction will be reported as an AE. Events captured on study specific forms (e.g., HADS) will not be recorded separately as an AE, unless they meet the SAE definition. Any of these events that meet the definition of an SAE, during the reporting periods described below, will be reported on the AE/SAE form set.

Adverse Events and Serious Adverse Events:

For the purpose of this study and if not described above, these events are required to be reported as an AE/SAE:

- All deaths that occur in either the Mother or the Infant (SAE)
- Congenital anomaly observed (SAE)
- Other infant SAEs that occur in breastfed infants
- All maternal AEs/SAEs while on study, except as noted below in “Events that do not require AE/SAE reporting”
- Maternal hospital re-admission within 6 weeks of delivery (SAE)
- Any ICU admission during the Labor and delivery admission (SAE)
- An opioid overdose resulting in naloxone rescue (SAE)

Events that do not require AE/SAE reporting:

- Hospitalization for Labor and Delivery, unless the hospitalization results in an ICU admission
- Prolongation of the hospital stay for a delivery (unless greater than 4 days for vaginal delivery or 7 days for C-section delivery)
- Admission to a hospital for elective surgery or pre-scheduled diagnostic tests
- Opioid overdose, unless resulting in naloxone rescue, hospitalization, or death
- Infant AEs and SAEs, except infant deaths, congenital anomalies in all infants, , and other infant SAEs in breastfed infants

11.17.3 Medical Monitor

The CCC Safety Monitor/Medical Monitor is responsible for reviewing all adverse events and serious adverse events reported. All SAEs will be reviewed within one business day of being reported in Advantage eClinical. The Medical Monitor will also indicate concurrence or not with the details of the report provided by the site PI. Where further information is needed the Safety Monitor/Medical monitor will discuss the event with the site. Reviews of SAEs will be conducted in the Advantage eClinical data system and will be a part of the safety database. All AEs are reviewed on a regular basis to observe trends or unusual events. The CCC Safety Monitor/Medical Monitor will in turn report events to the sponsor and regulatory authorities if the event meets the definition of an expedited event. Reports will be generated and presented for DSMB meetings.

Standard definitions for adverse events and serious adverse events, their identification, characterization regarding severity and relationship to therapy and processing are described in Appendix A.

11.17.4 Known Potential Toxicities of Study Medication/Intervention

Refer to the investigator's brochure for CAM2038, and package inserts for buprenorphine, and buprenorphine/naloxone.

11.18 Training Requirements

A comprehensive Training Plan will be developed to incorporate general training, study-specific training, mechanisms for competency assessment as well as a detailed description of training, supervision, and fidelity monitoring procedures. The Investigative Team is responsible for the development of a comprehensive Training Plan, instructional material, and delivery of the training, with the team comprised of the Lead Node, CCC, DSC, as well as other participating nodes and subject matter experts, as applicable.

The CTN-0080 study staff will be trained as specified in the study Training Plan. Training will include Human Subjects Protection and GCP as well as protocol-specific training on assessments, medication management for pharmacological studies, study interventions, safety and safety event reporting, study visits and procedures, data management, quality assurance, laboratory procedures, etc. The Lead Node is primarily responsible for development and delivery of study-specific training related to the study intervention(s) and procedures. The CCC is responsible for the development and delivery of non-intervention training, including regulatory and laboratory procedures, safety and safety event reporting, quality assurance and monitoring, etc. The DSC is responsible for training related to data management, the electronic data capture system, and good data management practices. Other parties will contribute as needed based on the subject matter and material to be covered. The various sub-teams will collaborate to deliver quality instructional material designed to prepare research staff to fully perform study procedures based on the assigned research roles and responsibilities.

In addition to general and study-specific training, the Training Plan will include a description of the delivery methods to be used for each training module (e.g., via self-study, online, webcast, or teleconference). Study staff is required to complete institutionally-required training per their research site, IRB, and authorities with regulatory oversight. Tracking of training completion for individual staff as prescribed for assigned study role(s) will be documented, endorsed by the site PI and the Lead Node, and audited by the CCC. As changes occur in the prescribed training, the Training Plan and training documentation tracking forms will be amended to reflect these adjustments.

12.0 DATA MANAGEMENT AND PROCEDURES

12.1 Design and Development

This protocol will utilize a centralized Data and Statistics Center (DSC) for participant data. The DSC will be responsible for the development of the CRFs, development and validation of the clinical study database, ensuring data integrity, and training site and participating node staff on applicable data management procedures. Ideally, a web-based distributed data entry model will be implemented. This system will be developed to ensure that guidelines and regulations surrounding the use of computerized systems used in clinical trials are upheld. The remainder of this section provides an overview of the data management plan associated with this protocol.

12.1.1 Site Responsibilities

The data management responsibilities of each individual site will be specified by the Lead Node and the DSC.

12.1.2 Data Center Responsibilities

The DSC will: 1) develop and apply a data management plan and will conduct data management activities in accordance with that plan; 2) provide final guided source documents and eCRFs for the collection of all participant data required by the study; 3) develop data dictionaries for each eCRF that will comprehensively define each data element; 4) conduct ongoing data monitoring activities on study data from all participating sites; 5) monitor any preliminary analysis data cleaning activities as needed, and 6) rigorously monitor final study data cleaning.

12.1.3 Data Collection

The data collection process consists of data collected on source documents and entered by the site into eCRFs in Advantage eClinical, direct data entry at the time of visit into Advantage eClinical and upload of specimen results into Advantage eClinical. In the event that Advantage eClinical is not available, the DSC will provide the sites with a final set of guided source documents and completion instructions. Data entry into Advantage eClinical should be completed according to the instructions provided and project specific training. The investigator is responsible for maintaining accurate, complete, and up-to-date records, and for ensuring the completion of the eCRFs for each research participant.

12.2 Data Acquisition and Entry

Completed forms and electronic data should be entered into the data management system in accordance with the CRF Completion Guidelines established by the DSC. Only authorized individuals shall have access to electronic CRFs.

12.3 Data Editing

Data will be entered into the DSC automated data acquisition and management system. Dynamic reports listing missing values and forms are available to sites at all times in Advantage eClinical. These reports will be monitored regularly by the DSC. Additionally, if incomplete or inaccurate data are found, a query will be generated to the sites for a response. Sites will resolve data inconsistencies and errors and enter all corrections and changes into Advantage eClinical.

12.4 Database Transfer/Lock

The DSC will conduct final data quality assurance checks and "lock" the study participant database from further modification at the end of the 12-month postpartum phase and at the end of the INO sub-study. Additionally, the data may be soft locked or frozen at the completion of each of the screening and pregnancy phases. The final analysis dataset will be returned to NIDA, as requested, for storage and archive.

12.5 Data Sharing

Data will be transmitted by the DSC to the designated party for de-identification, posting, storing, and archiving on NIDA's Data Share website. Data Share is an online repository of data from studies funded by the NIDA and is located at: <https://datashare.nida.nih.gov/>.

12.6 Data Training

The training plan for site staff includes provisions for training on assessments, CRF completion guidelines, and computerized systems.

12.7 Data QA

To address the issue of data quality, the DSC will follow a standard data monitoring plan. An acceptable data quality level prior to any database lock will be given as part of the data management plan. Data quality summaries will be made available during the course of the study.

13.0 PUBLIC ACCESS AND DATA SHARING PLAN

This study will comply with the NIH Data Sharing Policy and Implementation Guidance (https://grants.nih.gov/grants/policy/data_sharing/data_sharing_guidance.htm) and the HEAL Public Access and Data Sharing Policy (<https://www.nih.gov/research-training/medical-research-initiatives/heal-initiative/research/heal-public-access-data-sharing-policy>). Investigators will also register and report results of the trial in ClinicalTrials.gov, consistent with the requirements of the Policy on the Dissemination of NIH-Funded Clinical Trial Information and the Clinical Trials Registration (<https://grants.nih.gov/policy/clinical-trials/reporting/understanding/nih-policy.htm>).

Primary data for this study will be available to the public in the NIDA data repository, per NIDA CTN policy. For more details on data sharing please visit <https://datashare.nida.nih.gov/>.

The primary outcome(s) publication will be included along with study underlying primary data in the data share repository, and it will also be deposited in PubMed Central <http://www.pubmedcentral.nih.gov/> per NIH Policy (<http://publicaccess.nih.gov/>).

Every attempt will be made to publish results in peer-reviewed journals. The planning, preparation, and submission of publications will follow the policies of the Publications Committee of the CTN. Considerations for ensuring confidentiality of any shared data are described in **section 11.7**.

ACKNOWLEDGEMENT BY INVESTIGATOR:

- I am in receipt of version 8.0 of the protocol and agree to conduct this clinical study in accordance with the design and provisions specified therein.
- I agree to follow the protocol as written except in cases where necessary to protect the safety, rights, or welfare of a participant, an alteration is required, and the sponsor and IRB have been notified prior to the action.
- I will ensure that the requirements relating to obtaining informed consent and institutional review board (IRB) review and approval in 45 CFR 46 are met.
- I agree to personally conduct or supervise this investigation at this site and to ensure that all site staff assisting in the conduct of this study are adequately and appropriately trained to implement this version of the protocol and that they are qualified to meet the responsibilities to which they have been assigned.
- I agree to comply with all the applicable federal, state, and local regulations regarding the obligations of clinical investigators as required by the Department of Health and Human Services (HHS), the state, and the IRB.

16.0 APPENDIX A: ADVERSE EVENT REPORTING AND PROCEDURES

Each participating site's Principal Investigator is responsible for study oversight, including ensuring human research subject protection by designating appropriately qualified and trained study personnel to assess, report, and monitor adverse events.

Definition of Adverse Events and Serious Adverse Events

An **adverse event** (AE) is any untoward medical occurrence in humans, whether or not considered study medication related which occurs during the conduct of a clinical trial. Any change from baseline in clinical status, ECGs, lab results, x-rays, physical examinations, etc., that is considered clinically significant by the study medical clinician are considered AEs.

Suspected adverse reaction is any adverse event for which there is a reasonable possibility that the study medication caused the adverse event. A reasonable possibility implies that there is evidence that the study medication caused the event.

Adverse reaction is any adverse event caused by the study medication.

An **adverse event, suspected adverse reaction, or adverse reaction** is considered "**serious**" (i.e., a serious adverse event, serious suspected adverse reaction or serious adverse reaction) if, in the view of either the study medical clinician or sponsor, it:

1. Results in death: A death occurring during the study or which comes to the attention of the study staff during the protocol-defined follow-up period, whether or not considered caused by the study medication, must be reported.
2. Is life-threatening: Life-threatening means that the study participant was, in the opinion of the medical clinician or sponsor, at immediate risk of death from the reaction as it occurred and required immediate intervention.
3. Requires inpatient hospitalization or prolongation of existing hospitalization.
4. Results in persistent or significant incapacity or substantial disruption of the ability to conduct normal life functions.
5. Is a congenital abnormality or birth defect.
6. Is an important medical event that may not result in one of the above outcomes, but may jeopardize the health of the study participant or require medical or surgical intervention to prevent one of the outcomes listed in the above definition of serious event.

Definition of Expectedness

Any adverse event is considered "unexpected" if it is not listed in the investigator's brochure or the package insert or is not listed at the specificity or severity that has been observed. If neither is available, then the protocol and consent are used to determine an unexpected adverse event.

Medical and Psychiatric History

A thorough medical and psychiatric history during the baseline phase should record any chronic, acute, or intermittent preexisting or current illnesses, diseases, symptoms, or laboratory signs of

the participant, to avoid reporting pre-existing conditions as new AEs and to assist in the assessment of worsening in intensity or severity of these conditions that would indicate an AE. Stable chronic conditions, such as arthritis, which are present prior to clinical trial entry and do not worsen are not considered AEs.

Site's Role in Eliciting and Reporting Adverse Events

Appropriately qualified and trained personnel will elicit participant reporting of AEs and SAEs at each study visit designated to collect AEs. Adverse events (medical and/or psychiatric) assessment will initiate with participant consent and follow-up of reported AEs will continue through 30 days post last study visit. Study personnel will obtain as much information as possible about the reported AE/SAE to complete the AE/SAE forms and will consult as warranted.

Standard reporting, within 7 days of the site becoming aware of the event, is required for reportable AEs. Expedited reporting (within 24 hours of their occurrence and/or site's knowledge of the event) is required for reportable SAEs (including death and life-threatening events). Local sites are responsible for reporting SAEs to the IRB of record, per the IRB of record's guidelines.

Sites are required to enter reportable AEs and SAEs in the Advantage eClinical system. The AE form is used to capture reportable AEs and SAEs (as defined in the protocol). Additional information may need to be gathered to evaluate SAEs and to complete the appropriate CRFs and the summary. This process may include obtaining hospital discharge reports, medical records, autopsy records or any other type records or information necessary to provide a complete and clear picture of the serious event and events preceding and following the event. If the SAE is not resolved or stable at the time of the initial report or if new information becomes available after the initial report, follow-up information must be submitted as soon as possible.

Reportable adverse events will be followed until resolution, stabilization or study end. Any serious adverse reactions will be followed until resolution or stabilization even beyond the end of the study.

Site's Role in Assessing Severity and Causality of Adverse Events

Appropriately qualified and trained study personnel will conduct an initial assessment of seriousness, severity, and causality when eliciting participant reporting of adverse events. A study medical clinician will review reportable AEs for seriousness, severity, and causality on at least a weekly basis.

Guidelines for Assessing Severity

The severity of an adverse event refers to the intensity of the event:

Grade 1	Mild	Transient or mild discomfort (typically <48 hours), no or minimal medical intervention/therapy required, hospitalization not necessary (non-prescription or single-use prescription therapy may be employed to relieve symptoms, e.g., aspirin for simple headache, acetaminophen for post-surgical pain)
Grade 2	Moderate	Mild to moderate limitation in activity, some assistance may be needed; no or minimal intervention/therapy required, hospitalization possible.
Grade 3	Severe	Marked limitation in activity, some assistance usually required; medical intervention/ therapy required, hospitalization possible.

Guidelines for Determining Causality

The study medical clinician will use the following question when assessing causality of an adverse event to study medication where an affirmative answer designates the event as a suspected adverse reaction:

Is there a reasonable possibility that the study medication caused the event?

Site's Role in Monitoring Adverse Events

Local quality assurance monitors will review study sites and respective study data on a regular basis and will promptly advise sites to report any previously unreported safety issues and ensure that the reportable safety-related events are being followed to resolution and reported appropriately. Staff education, re-training or appropriate corrective action plan will be implemented at the participating site when unreported or unidentified reportable AEs or serious events are discovered, to ensure future identification and timely reporting by the site.

Sponsor's Role in Safety Management Procedures of AEs/SAEs

A NIDA-assigned Medical Monitor is responsible for reviewing all serious adverse event reports. All reported SAEs will generate an e-mail notification to the Medical Monitor, Lead Investigator, and designees. All SAEs will be reviewed by the Medical Monitor in Advantage eClinical and, if needed, additional information will be requested. The Medical Monitor will also report events to the sponsor, pharmaceutical company (Braeburn), and the DSMB. The DSMB will receive summary reports of all adverse events annually, at a minimum. The DSMB or the NIDA assigned Medical Monitor may also request additional and updated information. Details regarding specific adverse events, their treatment and resolution, will be summarized by the Medical Monitor in writing for review by the sponsor and DSMB. Subsequent review by the Medical Monitor, DSMB, FDA and ethics review committee or IRB, the sponsor, or relevant local regulatory authorities may also suspend further trial treatment at a site. The study sponsor, DSMB and FDA retain the authority to suspend additional enrollment and treatments for the entire study as applicable.

Reporting to the Data and Safety Monitoring Board

The DSMB will receive listings of AEs and summary reports of all SAEs at a frequency requested by the DSMB, but at least annually. Furthermore, the DSMB will be informed of expedited reports of SAEs.

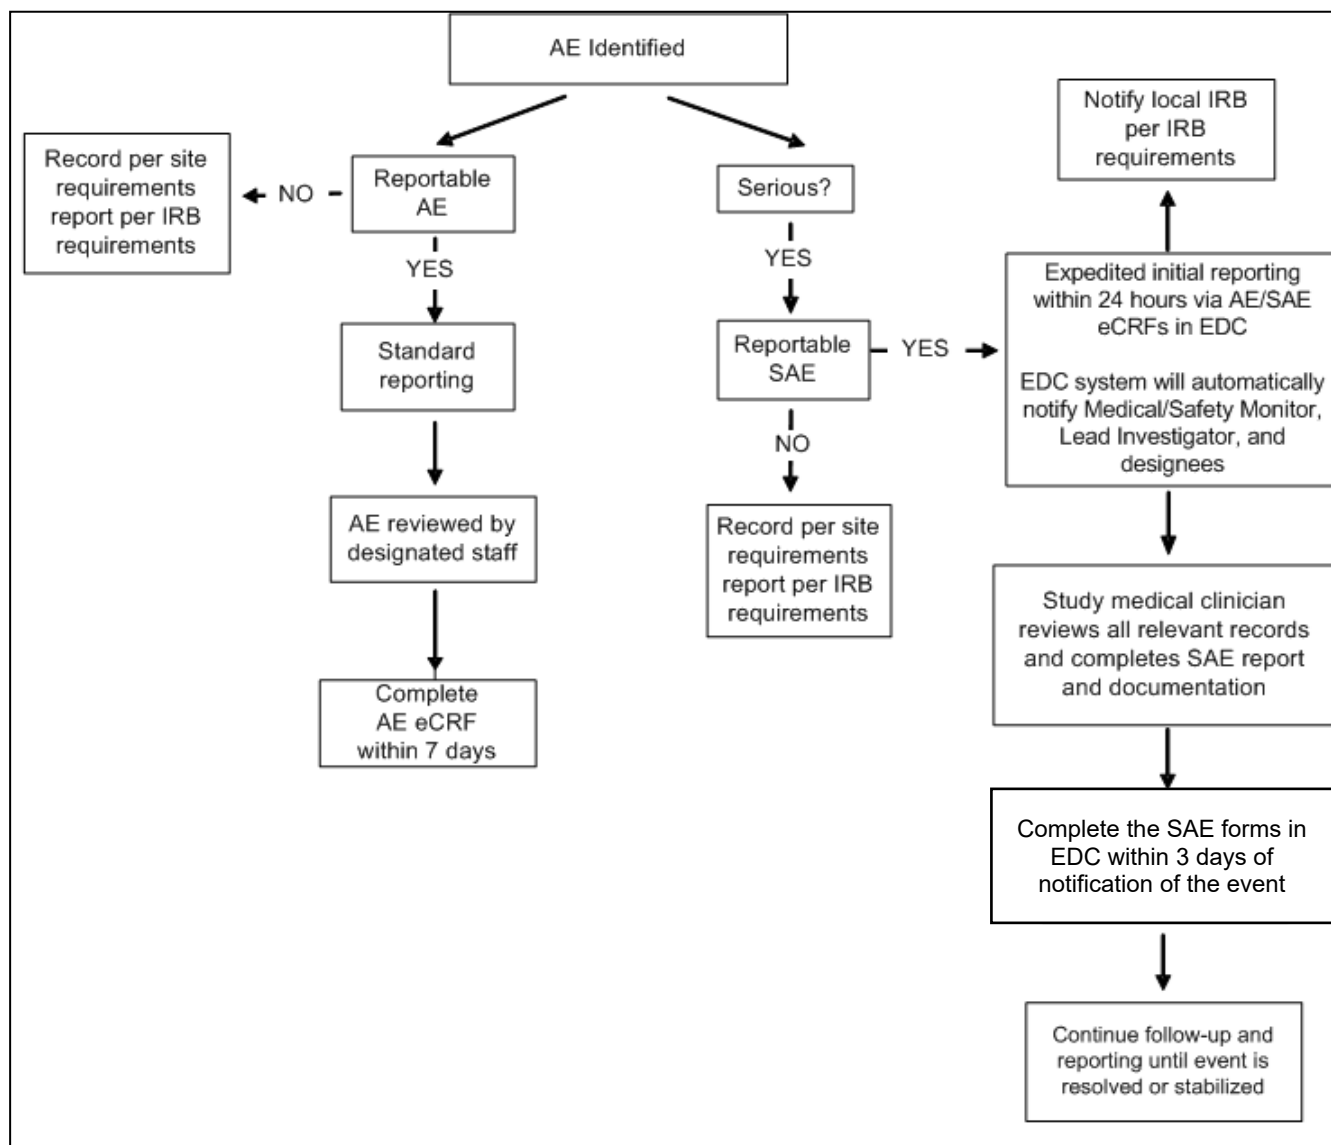

Regulatory Reporting for an IND study

All serious and unexpected suspected adverse reactions are reported by the medical monitor on behalf of the sponsor to the FDA in writing within 15 calendar days of notification. Suspected adverse reactions that are unexpected and meet the criteria for death or immediately life-threatening also require notification of the FDA as soon as possible but no later than 7 calendar days of notification of the event, with a follow-up written report within 15 calendar days of notification of the event. The medical monitor will prepare an expedited report (MedWatch Form 3500A or similar) for the FDA and other regulatory authorities, DSMB and copies will be distributed to all sites. Expedited reports will be placed in the site regulatory files upon receipt. A copy of all expedited reports will be forwarded to the site's local IRB, as required.

Participant Withdrawal

The study medical clinician must apply his/her clinical judgment to determine whether or not an adverse event is of sufficient severity to require that the participant be withdrawn from further study medication administration. The study medical clinician should consult with the site Principal Investigator, the Lead Investigator and/or Medical Monitor as needed. If necessary, a study medical clinician may suspend any trial treatments and institute the necessary medical therapy to protect a participant from any immediate danger. A participant may also voluntarily withdraw from treatment due to what he/she perceives as an intolerable adverse event or for any other reason. If voluntary withdrawal is requested, the participant will be asked to complete an end-of-medication visit to assure safety and to document end-of-medication outcomes and will be given recommendations for medical care and/or referrals to treatment, as necessary.

Adverse Event Reporting (Chart)

17.0 APPENDIX B: DATA AND SAFETY MONITORING PLAN

17.1 Brief Study Overview

17.1.1 Protocol Description

The primary objective of this trial is to evaluate the impact of treating opioid use disorder (OUD) in pregnant women with extended-release (XR) buprenorphine (BUP), compared to sublingual (SL) BUP, on mother and infant outcomes. It is hypothesized that the BUP-XR, relative to the BUP-SL, group will: 1) not have greater illicit opioid use during pregnancy (primary, non-inferiority); 2) have lower infant neonatal opioid withdrawal syndrome (NOWS) severity (key secondary, superiority); and 3) not have greater postpartum illicit opioid use (key secondary, non-inferiority). Testing conceptual models of the mechanisms by which BUP-XR may improve mother-infant outcomes, relative to BUP-SL, is a secondary objective. Determining the economic value of BUP-XR, compared to BUP-SL, to treat pregnant women is a tertiary objective. A final objective is evaluating the impact of BUP-XR, relative to BUP-SL, on infant neurodevelopment.

17.1.2 Key outcome measures

Mother key outcomes include illicit opioid abstinence during pregnancy and postpartum, assessed by urine drug screens (UDSs). Total days of infant opioid treatment, derived from the infant's medical record, is the infant key outcome. The Conceptual Model Assessment (CMA) sub-study includes assessments of: 1) maternal trough BUP plasma concentrations at study weeks 3 and 5; 2) fetal non-stress test and biophysical profile at ~36 weeks EGA at maternal peak BUP plasma level; 3) maternal peak and trough BUP plasma concentrations at ~36 weeks EGA; and 4) cord plasma BUP/BUP-metabolite levels. The main economic outcome will be the incremental cost-effectiveness ratio (ICER). The main outcome for the INO sub-study is the score on the cognitive subscale of the Bayley™-4 at 24 months of age.

17.1.3 Inclusion/Exclusion Criteria:

All potential participants will be recruited from participating sites. Eligible participants will meet all inclusion, and no exclusion criteria:

Inclusion Criteria:

Potential participants must:

1. be 18-41 years of age;
2. be pregnant with an EGA of 6 - 30 weeks at randomization, have evidence of a viable intrauterine pregnancy if EGA <12 weeks, and are not planning to terminate the pregnancy;
3. have a single fetus pregnancy (can be based on self-report if an objective assessment is unavailable);
4. meet DSM-5 criteria for moderate/severe OUD and be a good candidate for BUP maintenance and/or be currently prescribed BUP for the treatment of OUD;
5. be willing to be randomized to BUP-XR or BUP-SL and to comply with study procedures, including weekly Medication Check Visits;
6. be planning to deliver at one of the hospitals for which the BORN survey was completed and that: a) has a written protocol for the management of NAS/NOWS, b) offers

rooming-in while infants are being observed for NAS/NOWS; and c) does not send infants home on opioids for the treatment of NAS/NOWS;

7. be enrolled in outpatient addiction treatment at a participating site (e.g., have completed intake);
8. be able to understand the study, and having understood, provide written informed consent in English.

Exclusion Criteria:

Potential participants must not:

1. have a physiological dependence on alcohol or sedatives requiring medical detoxification;
2. have a psychiatric condition that, in the judgment of the site medical clinician (MC), would make study participation unsafe or which would make treatment compliance difficult;

Examples include:

- Suicidal or homicidal ideation requiring immediate attention
 - Severe, inadequately-treated mental health disorder (e.g., active psychosis, uncontrolled bipolar disorder)
3. have a medical condition that, in the judgment of the site MC, would make study participation unsafe or which would make treatment compliance difficult. Medical conditions that may compromise participant safety or study conduct include, but are not limited to, allergy/sensitivity to study medications and the following based on clinical labs:
 - AST/ALT greater than 5X upper limit of normal
 - serum creatinine greater than 1.5X upper limit of normal
 - total bilirubin greater than 1.5X upper limit of normal
 4. be currently in jail, prison or any inpatient overnight facility as required by court of law or have pending legal action or other situation (e.g., unstable living arrangements) that, in the judgement of the site investigator, could prevent participation in the study or in any study activities;
 5. be currently receiving methadone or naltrexone for treatment;
 6. be enrolled in or planning to enroll in treatment beyond the level of 3.1 (clinically managed low-intensity residential services) of the American Society of Addiction Medicine criteria;¹⁰³
 7. be enrolled in or planning to enroll in: a) a trial testing medication for managing OUD during pregnancy; b) research testing an intervention for substance use disorder or NOWS in their infant unless they are willing to provide a release for the research records.

17.1.4 Sample Size

Approximately 200 participants, recruited from approximately 10 sites, will be randomized into the trial.

17.1.5 Overview of Protocol Monitoring

Four separate entities will be involved in the monitoring of this study — the participating CTN Nodes, the Lead Node, the Data and Statistics Center (DSC - Emmes), and the Clinical Coordinating Center (CCC - Emmes). All aspects of the study will be carefully monitored with respect to current good clinical practices. A study-specific QA plan will be developed to include

standard reporting templates for use by local monitoring teams. The following includes a summary of the responsibilities for each team.

The CTN nodes will be responsible for completing monitoring activities in accordance with the study QA plan during the pre-initiation, recruitment, enrollment, follow up, and close-out phases. These activities will be conducted by local QA monitors located at each Node and aim to provide management support to the site research team in order to ensure adherence to the protocol, SOPs, and regulatory requirements and accurate data entry. Qualified node personnel will provide site management for each site during the trial. This will take place as often as needed to help prevent, detect, and correct problems at the study sites.

The Lead Node will provide on-going monitoring of study progress through review of weekly enrollment reports, as well as by reviewing monitoring reports from both local and CCC/Emmes monitors and regular data reports from the DSC/Emmes. The Lead Node will hold regular study management meetings to monitor any emergent problems or ongoing problematic trends, and may additionally hold individual meetings with site staff in order to assist in resolving any site-specific problems that impact the study. The Data and Statistics Center (DSC/Emmes) will conduct on-going monitoring of data completeness, accuracy, and quality through the use of reports within Advantage eClinical and regularly generated trial progress and data status reports. The Clinical Coordinating Center (CCC/Emmes) will focus on providing study monitoring to specifically address areas of regulatory compliance, safety compliance, source document verification and specific study related monitoring addressed below in the project detail. The four monitoring entities will aim to communicate and work together in scheduling visits (in order to avoid overlapping visits) and to cover a broad sample of study participants by auditing different participants to the extent possible.

17.2 Oversight of Clinical Responsibilities

17.2.1 Site Principal Investigator (PI)

Each participating site's PI is responsible for study oversight, including ensuring maintenance of secure study medication supply and human research subject protection by designating appropriately qualified, trained research staff and medical clinicians to assess, report, and monitor adverse events.

All adverse events (AEs) occurring during the course of the clinical trial will be collected, documented, and reported by the investigator or sub-investigators according to the Protocol.

The occurrence of AEs and serious adverse events (SAEs) will be assessed at each clinic visit during the study. SAEs will be followed until resolved or considered stable.

Reportable AEs are required to be entered into the data system within 7 days of the site staff becoming aware of the event. Reportable SAEs (including death and life-threatening events) are required to be entered into data system within 24 hours of site's knowledge of the event).

17.2.2 CCC Medical Monitor

The NIDA CTN Clinical Coordinating Center's (CCC) Medical Monitor or designee is responsible for reviewing all adverse events and serious adverse events reported. The CCC Medical Monitor is alerted via email each time an SAE is reported in the EDC. All SAEs will be reviewed at the time they are reported in the EDC. The Medical Monitor or designee will also indicate concurrence or not with the details of the report provided by the site PI. Where further information is needed,

the Medical Monitor or designee will discuss the event with the site staff. Reviews of SAEs by the CCC Medical Monitor or designee will be documented in the Advantage eClinical data system and will be a part of the safety database. All AEs are reviewed on a weekly basis to observe trends or unusual events.

17.2.3 Mandatory Regulatory Reporting in IND Trials

For trials conducted under IND, the CCC Medical Monitor or designee will report events to the regulatory authorities if the event meets the definition of an expedited event (21CFR312.32). All SAEs that meet expedited reporting will be reported to the FDA/Regulatory Authorities in writing within 15 calendar days of notification of the CCC. If the SAE also meets the criteria for death or immediately life-threatening, the CCC will notify the FDA/Regulatory Authorities electronically, by phone or by fax as soon as possible but no later than 7 calendar days of notification of the CCC pharmacovigilance team, with a follow-up written report within 15 calendar days of notification of the CCC. The CCC pharmacovigilance team will prepare an expedited report (MedWatch Form 3500A or similar) for the FDA/Regulatory authorities and copies will be distributed to all participating site investigators.

17.3 Data and Safety Monitoring Board (DSMB)

The NIDA CTN DSMB affiliated with this trial will be responsible for conducting periodic reviews of accumulating safety, trial performance, and outcome data. Reports will be generated and presented for Data and Safety Monitoring Board (DSMB) meetings. The DSMB will receive listings of reportable AEs and summary reports of all SAEs at a frequency requested by the DSMB, but at least annually. Furthermore, the DSMB will be informed of expedited reports of SAEs. The DSMB will make recommendations to NIDA CCTN as to whether there is sufficient support for continuation of the trial, evidence that study procedures should be changed, or evidence that the trial (or a specific site) should be halted for reasons relating to safety of the study participants or inadequate trial performance (e.g., poor recruitment).

Following each DSMB meeting, the NIDA CCTN will communicate the outcomes of the meeting, based on DSMB recommendations, in writing to the study Lead Investigator. This communication summarizing study safety information will be submitted to participating sites and the study IRB.

17.4 Quality Assurance (QA) Monitoring

The Lead Team has developed a study-specific QA Plan for the guidance of QA activities in this study. The monitoring of the study site(s) will be conducted on a regular basis using a combination of NIDA CCTN CCC monitors and the local Node QA Monitors. Investigators will host periodic visits for the NIDA CCTN CCC monitors and local Node QA Monitors. The purpose of these visits is to assess compliance with the protocol, GCP requirements, and other applicable regulatory requirements, as well as to document the integrity of the trial progress. The investigative site will provide direct access to all trial related sites (e.g., pharmacy, research office), source data/documentation, and reports for the purpose of monitoring and auditing by the CCC and local Node monitors, as well as inspection by local and regulatory authorities. Areas of particular concern will be the review of inclusion/exclusion criteria, participant Informed Consent Forms, protocol adherence, safety monitoring, IRB reviews and approvals, regulatory documents, participant records, study drug accountability, and Principal Investigator supervision and involvement in the trial. The monitors will interact with the site staff to identify issues and re-train the site as needed to enhance research quality.

Both the Local Node monitors and the NIDA CCC monitors will complete written QA visit reports following their respective site visits. These reports will be sent to the site Principal Investigator, the study Lead Node, the CCC Protocol Specialist, and NIDA CCTN.

17.5 Management of Risks to Participants

17.5.1 Confidentiality

Confidentiality of participant records will be secured by the use of study codes for identifying participants on CRFs, secure transportation of documents while performing study visits at any off-site location, and secure storage of any documents that have participant identifiers on site, as well as secure computing procedures for entering and transferring electronic data. The documents or logs linking the study codes with the study participant on site will be kept locked separately from the study files and the medical records. No identifying information will be disclosed in reports, publications or presentations.

17.5.2 Information That Meets Reporting Requirements

The consent forms will specifically state the types of information that are required for reporting and that the information will be reported as required. These include suspected or known sexual or physical abuse of a child or elders, or threatened violence to self and/or others.

17.5.3 Participant Protection

The site's Physician/Medical Clinician will evaluate all pertinent screening and baseline assessments prior to participant randomization to ensure that the participant is eligible and safe to enter the study. AEs and concomitant medications will be assessed and documented at each study visit. Individuals who experience an AE that compromises safe participation in the study, or who voluntarily wish to be discontinued from the study medication, will be safely and humanely discontinued from further study medication administration and provided referrals for other treatment or to specialized care. Study personnel will complete early termination of the study medication on a Medication Discontinuation form. In addition, study personnel will offer the participant an opportunity to continue study visits without medication; if the participant declines to continue study participation, study personnel will attempt to complete a final study visit to assure safety and to document end of treatment outcomes.

17.6 Pregnancy and Pregnancy Outcomes

Pregnancy outcomes will be captured as part of regular study data collection using information abstracted from the medical records for the participant and her neonate (if any). Pregnancy initiated in the 12-month post-partum period will not be considered an AE or SAE, but will be captured on a Pregnancy form.

17.7 Study Specific Risks

Both BUP-SL and BUP-XR are comprised of buprenorphine, which is an opioid medication. As such, withdrawal reactions may occur if the medication is discontinued abruptly. Prolonged use of opioids during pregnancy for medical or non-medical reasons can result in neonatal opioid withdrawal syndrome which may be life-threatening if not recognized and treated; however, research supports lower NAS/NOWS severity in the infants of mothers with opioid use disorder who are medically treated with BUP. Participants in this study will be provided with a medication information card that will notify clinicians that they are receiving BUP as part of this study.

17.8 Collection and management of AEs and SAEs

All adverse events (AEs) occurring during the course of the clinical trial will be collected, documented, and reported by the investigator or sub-investigators according to the Protocol.

The occurrence of AEs and serious adverse events (SAEs) will be assessed at each study visit following the initial screening visit. Serious adverse events will be followed until resolved or considered stable.

AEs are required to be entered into the data system within 7 days of the site staff becoming aware of the event. Reportable SAEs (including death and life-threatening events) are required to be entered into data system within 24 hours of site's knowledge of the event).

Serious Adverse Events (SAEs) will also be initially captured on the Adverse Events CRF. An SAE is defined as any event that occurs during the 'active' phase of treatment, or the follow-up periods, and either: (1) results in death, or (2) requires inpatient hospitalization (EXCEPT for the instances specified below) or a prolongation of existing hospitalization, or (3) is a congenital anomaly/birth defect, or (4) results in persistent or significant disability / incapacity, or (5) is life-threatening (EXCEPT for an opioid overdose not resulting in hospitalization or death), or (6) requires intervention to prevent one of the above outcomes.

For the purposes of this study, several exceptions to an episode of inpatient hospitalization will be specified and will not be reported as a Serious Adverse Event. These Exceptions are:

- (A) hospitalization for labor and delivery unless the hospitalization results in an ICU admission.
- (B) prolongation of the hospital stay for a delivery (unless greater than 4 days for vaginal delivery or 7 days for C-section delivery)
- (C) admission to a hospital for elective surgery or pre-scheduled diagnostic tests.

After capture on the AE CRF, the SAE form will be initiated by the research assistant (RA), and the following individuals will be notified within 24 hours of the site's initial receipt of the information: (1) the Investigator at the site (e.g., the Executive or Clinical Director, etc.), who will direct the appropriate review, then complete and sign the follow-up SAE Form, (2) the Node/Lead Node Regulatory staff person, who will notify the IRB according to their procedures, (3) the Project

Coordinator, (4) the Site Physician/Medical Clinician, who will review the event for relatedness to the study, and (5) the NIDA Medical Safety Officer, who will independently review each SAE for relatedness and expectedness.

Following the initial 24-hour SAE report, additional information will be gathered to enable an assessment of the event for relatedness. For example, psychiatric history, baseline severity of illness, treatment compliance, and verbal or objective information about drug use at the time of the event are pertinent. The site Investigator will attach copies of source documents to the follow-up SAE form, which will be forwarded to the NIDA Medical Safety Officer within 2 weeks of the initial SAE report. The NIDA Medical Safety Officer will accumulate individual SAE reports from all sites involved in the study and summarize them in a table of SAEs. The cumulative SAEs will be sent to the DSMB each quarter, to review for possible study-related toxicities. Recommendations from the DSMB will be communicated via NIDA in a summary letter to the LI; it is the LI's responsibility to forward this letter to the Node PIs, who in turn will convey it to their appropriate IRB(s).

17.9 Data Oversight

This protocol will utilize a centralized Data and Statistics Center (DSC). A web-based distributed data entry model will be implemented. This electronic data capture system (Advantage eClinical) will be developed to ensure that guidelines and regulations surrounding the use of computerized systems in clinical trials are upheld.

17.9.1 Data and Statistics Center Responsibility

The DSC will: 1) develop and apply data management procedures to ensure the collection of accurate and good-quality data, 2) provide source documents and electronic Case Report Forms (eCRFs) for the collection of all participant data required by the study, 3) develop data dictionaries for each eCRF that will comprehensively define each data element, 4) prepare instructions for the use of Advantage eClinical and for the completion of eCRFs, 5) conduct ongoing monitoring activities on study data collected from all participating sites, and 6) perform data cleaning activities prior to the final study database lock.

17.9.2 Data Collection and Entry

Data will be collected at the study visits on source documents and entered by the site into eCRFs in Advantage eClinical or will be collected via direct entry into the eCRF or will be uploaded from a central lab into Advantage eClinical. In the event that Advantage eClinical is not available, the DSC will provide the sites with paper source documents and completion instructions. Data will be entered into Advantage eClinical in accordance with the instructions provided during protocol-specific training and guidelines established by the DSC. Data entry into the eCRFs is performed by authorized individuals. Selected eCRFs may also require the investigator's electronic signature. In some situations, data collected on source documents will not be entered into Advantage eClinical, but when it is entered, it will follow the guidelines stated above.

The investigator at the site is responsible for maintaining accurate, complete and up-to-date research records. In addition, the investigator is responsible for ensuring the timely completion of eCRFs for each research participant.

17.9.3 Data Monitoring, Cleaning, and Editing

eCRFs will be monitored for completeness and accuracy throughout the study. Dynamic reports listing missing values and forms are available to sites at all times in Advantage eClinical. These

reports will be monitored regularly by the DSC. In addition, the DSC will identify inconsistencies within eCRFs and between eCRFs and post queries in Advantage eClinical on a scheduled basis. Sites will resolve data queries by entering all corrections and changes directly into Advantage eClinical or verifying the data are correct as is.

As described above, the CCC will conduct regular site visits, during which audits comparing source documents to the data entered on the eCRF will be performed. Any discrepancies identified between the source document and the eCRF will be corrected by the site.

Trial progress and data status reports, which provide information on recruitment, availability of primary outcome, treatment exposure, attendance at long term follow-up visits, regulatory status, and data quality, will be generated daily and posted to a secure website. These reports are available to the site, the corresponding Node, the lead investigator, the coordinating centers, and NIDA CCTN, to monitor the sites' progress on the study.

17.9.4 Database Lock and Transfer

At the conclusion of data collection for the study, the DSC will perform final data cleaning activities and will "lock" the study database from further modification. The final analysis dataset will be transferred to the Lead Investigator or designee. De-identified versions of these datasets will also be provided to the NIDA CCTN-designated parties for posting on Datashare, as well as storage and archiving. Results of the study will also be entered into www.clinicaltrials.gov by the Lead Investigative Team.

Reference: <http://grants.nih.gov/grants/guide/notice-files/not98-084.html>

18.0 APPENDIX C: REGULATORY

18.1 Single IRB

All study sites and corresponding IRBs not already part of the University of Cincinnati must agree to adhere to all policies outlined by The National Drug Abuse Treatment Clinical Trials Network (UG1) as indicated in RFA DA 15 008. UC has already agreed to adhere to this policy. Prior to confirmation of site selection, each site's IRB must provide, in writing, an agreement that they will be willing to rely on the UC IRB as the single IRB of record for this study, pending whatever local context reviews they perform.

18.2 Study Discontinuation

Individual study participants will be informed of their right to discontinue study participation at any time during the study. The PI may discontinue a participant from the trial if deemed clinically appropriate. The DSMB may recommend study termination based on review of site performance or safety and efficacy data. NIDA has the right to discontinue the investigation at any time.
