	Name, Degree	Institution Name
Principal Investigator, IDE Chair	Boris Kovatchev, PhD	University of Virginia Center for Diabetes Technology
Study Physician / Protocol Chair	Sue A. Brown, MD	University of Virginia Center for Diabetes Technology
Co-Investigator/ Study Engineer	Anas El Fathi, PhD	University of Virginia Center for Diabetes Technology

PROTOCOL VERSION HISTORY

Version Number	Author(s)	Approver	Effective Date	Revision Description
1.0	Boris Kovatchev	Sue Brown, Anas El Fathi	24-Oct-2024	Original Protocol
1.1	Boris Kovatchev	Boris Kovatchev	01-Nov-2024	FDA Revision 1 <ul style="list-style-type: none"> • Added compliance sentence (Chapter 1:) • Improved clarity that Remote Monitoring occurs during both At-Home studies (section Table 1, 2.5, 5.1, 7.2) • Replaced Statistical Consideration Chapter (Chapter 12:)
1.2	Mary Oliveri		19-Mar-2025	Study Team <ul style="list-style-type: none"> • Moved A1c from Visit 1 Screening Labs to Visit 2. • Participants asked to place a new sensor prior to Visit 2.

SITE PRINCIPAL INVESTIGATOR STATEMENT OF COMPLIANCE

Protocol Title: Safety and Feasibility of a Machine-Learning Bolus Priming Added to Existing Control Algorithm (AIDANET)

Running Title: AIDANET+Reinforcement Learning trained Bolus Priming System (AIDANET+BPS_RL)

Protocol Version/Date: v1.2/ 19-Mar-2025

I have read the protocol specified above. In my formal capacity as a Site Principal Investigator, my duties include ensuring the safety of the study participants enrolled under my supervision. It is understood that all information pertaining to the study will be held strictly confidential and that this confidentiality requirement applies to all study staff at this site.

This trial will be carried out in accordance with ICH E6 Good Clinical Practice (GCP) and as required by the following: United States (US) Code of Federal Regulations (CFR) applicable to clinical studies (45 CFR Part 46, 21 CFR Part 50, 21 CFR Part 56, 21 CFR Part 312, and/or 21 CFR Part 812).

As the Principal Investigator, I will assure that no deviation from, or changes to the protocol will take place without prior agreement from the sponsor and documented approval from the Institutional Review Board (IRB), or other approved Ethics Committee, except where necessary to eliminate an immediate hazard(s) to the trial participants.

All key personnel (all individuals responsible for the design and conduct of this trial) have completed Human Participants Protection Training and Good Clinical Practice Training. Further, I agree to ensure that all staff members involved in the conduct of this study are informed about their obligations in meeting the above commitments.

Investigator's Signature _____ Date: ____ / ____ / ____

LIST OF ABBREVIATIONS

Abbreviation	Definition
ADA	American Diabetes Association
AE	Adverse Event
AID	Automated insulin delivery
AIDANET	Automated insulin delivery as Adaptive Network
AP	Artificial pancreas
AUC	Area Under the Curve
AYA	Adolescent and Young Adult
BDC	Barbara Davis Center
BG	Blood Glucose (as assessed by a blood glucose meter)
BGM	Blood glucose meter
BPS	Bolus Priming System
CGM	Continuous glucose monitor
CSII	Continuous subcutaneous insulin infusion
DiAs	Diabetes Assistant
DKA	Diabetic Ketoacidosis
DWM	DiAs Web Monitoring
FCL	Fully automated closed-loop
HbA1c	Hemoglobin A1c
HCL	Hybrid closed loop
NAP	Neural-network artificial pancreas
RL	Reinforcement Learning
SAE	Severe Adverse Event
SG	Sensor Glucose (as assessed by a continuous glucose monitor)
SH	Severe Hypoglycemia
T1D	Type 1 diabetes
TAR	Time above range
TBR	Time below range
TIR	Time in range 70-180 mg/dL

PROTOCOL SUMMARY

Participant Area	Description
Title	Safety and Feasibility of a Machine-Learning Bolus Priming Added to Existing Control Algorithm (AIDANET)
Investigational Device	Reinforcement Learning trained Bolus Priming System (BPS_RL) added to the AIDANET algorithm and running on DiAs phone wirelessly connected to Tandem t:AP insulin pump and Dexcom CGM
Objectives	The primary objective of the project is to demonstrate feasibility and safety of the BPS_RL added to the existing AIDANET AID algorithm, used in FCL mode by adults with T1D.
Study Design	A randomized cross-over trial assessing glycemic control on AIDANET+ BPS_RL, compared to the original AIDANET algorithm, which includes two sessions studied in a supervised hotel setting: 1) using AIDANET+ BPS_RL, and 2) using the original AIDANET without modifications including the previous BPS (see IDE G240236).
Number of Sites	1
Endpoint	The primary outcome will be time in range 70-180 mg/dL for an 18-hour period, 6 PM to 12 PM on the next day, including dinner and breakfast meals.
Population	Key Inclusion Criteria: <ul style="list-style-type: none"> • Age ≥ 18 years of age • Clinical diagnosis, based on investigator assessment, of Type 1 Diabetes for at least 1 year • Currently using insulin for at least six months. • Having used an AID system equipped with Dexcom G6 or G7 sensor within the last 3 months
Sample Size	Complete 16 participants
Treatment Groups	Randomized crossover: Participants will be randomized to two groups differing by the order of controller use: Group A: AIDANET first followed by AIDANET+ BPS_RL; Group B: AIDANET+ BPS_RL followed by AIDANET.
Participant Duration	Approximately 3 weeks, including: 1 week of remotely monitored AIDANET at home for all participants, 3 days/2 nights AIDANET vs. AIDANET+ BPS_RL crossover at a hotel, and 1 week at home remote monitored AIDANET+ BPS_RL for all participants (Figure 1).
Protocol Overview/Synopsis	Following enrollment, 1 week of AIDANET data will be collected and will be used to establish a baseline and initialize the control algorithm. Participants will be then studied at a hotel for approximately 40 hours, including two 18-hour experiments, randomly receiving either AIDANET or AIDANET+ BPS_RL. Participants will then receive the opposite intervention sequentially during the same hotel session and will then transition to 1-week remote monitored home use of AIDANET+ BPS_RL (Figure 1).

Chapter 1: Background and Introduction

Automated Insulin Delivery (AID) has firmly transitioned to the clinical practice of Type 1 Diabetes (T1D) and has made its first strides into insulin-using type 2 diabetes as well. High-ranking general medicine journals are now regularly publishing AID clinical trials.¹⁻⁶ Real-life data for thousands of AID users have been published, consistently showing the superiority of AID over standard therapies.⁷⁻¹³ Consensus recommendations for the use of automated insulin delivery technologies in clinical practice were published by Endocrine Reviews,¹⁴ to serve as a comprehensive guide for clinicians interested in utilizing the advantages of AID therapy.

The “brain” of any insulin delivery system is a control algorithm, which digests information from peripheral devices, e.g., a continuous glucose monitor (CGM) and insulin pump, and then directs the pump to deliver amounts of insulin that are considered optimal. Typically, this happens at a pace of every few minutes;¹⁵ thus an AID control algorithm has to be fast, efficient, and with low computational demands, particularly because the data processing is done by a device with low computing power, such as an insulin pump or a smart watch. The early studies of Hovorka^{16,17} and Steil¹⁸ outlined two major types of algorithms now in use – model-predictive control (MPC)¹⁷ and proportional-integral-derivative (PID).¹⁸ A modular controller based on the user’s state estimation was introduced in 2009,¹⁹ which later became the algorithm behind Tandem’s Control-IQ AID system.^{1,2,4,7} In 2010, two new algorithms were introduced: Zone MPC²⁰ – a strategy to minimize hyper- and hypoglycemic events, and MD Logic using clinical knowledge and fuzzy logic models to drive insulin delivery.²¹ In combination with PID, MD Logic powered the MiniMED Advanced Hybrid Closed-Loop (AHCL) system.^{22,23} A MPC-PID mix was introduced to drive dual-hormone AP²⁴, and is now used in studies with the dual-chamber iLet pump.²⁵ Overall, a PubMed search on artificial pancreas, or AID, or closed loop algorithms, identified 555 papers proposing AID controllers. To date, at least 6 of them have been implemented in devices used in clinical practice.

However, virtually all contemporary AID algorithms rely on approximations of the human metabolic system by equations (in the case of PID) or by a model, in the case of MPC.¹⁵ Empirical controllers have been introduced as well, incorporating clinical knowledge in the insulin dosing decision making process.²¹ Adaptive AID algorithms have been introduced over the years, attempting to compensate for the ever-changing physiology of their users.²⁶⁻²⁹ This is typically done by using a person’s data from the previous hours/days/weeks and re-estimating accordingly the parameters of the model underlying the control algorithm. Mathematically, such re-estimation requires rather complex numerical methods, as closed-form solutions rarely exist. As a result, contemporary adaptive algorithms cannot run on devices with low processing power, such as insulin pumps. In some cases, such as the CamAPS AID system, the demand for computing power is satisfied by placing the control algorithm on a smart phone.³⁰ But, integrated AID devices that do not rely on external computing resources, e.g. AHCL,^{22,23} \Control-IQ^{1,2,4,7} and \Omnipod 5,³¹ cannot afford running complex nonlinear algorithms.

To summarize, the current AID systems face two major shortcomings: (1) Any learning or adaptation of the AID algorithm is based only on the data patterns of this algorithm’s user and does not have a mechanism to utilize the vast amounts of data collected in various databases, and (2) Any learning or adaptation of the AID algorithm requires substantial computing power.

Contemporary Data Science methods, such as machine learning and AI, can remedy both of these shortcomings. The first step towards that end was translating an established AID control algorithm, into a Data Science “environment,” e.g., creating a neural network approximation of a model-predictive controller. In early 2024, we conducted a pilot-feasibility study of a conceptually new AID algorithm – a Neural-network artificial pancreas (NAP) that was a result from a process of encoding an insulin dosing rule into a neural network – clinicaltrials.gov ID NCT05876273, IDE #G230052.³² This process was based on the concept of a “Saturated Dataset”, e.g., an ensemble of examples of the dosing rule computation that is sufficiently dense and sufficiently wide, so that the deviation between the original dosing rule and the resulting neural network is kept within predefined limits.³³ If the preset limits are sufficiently small, the neural net can be considered a safe and efficacious alternative to the original dosing rule. The results from this first randomized crossover study showed that the NAP concept works as intended – all predefined conditions for success, i.e., proximity of NAP to its original UMPC algorithm, were met.³² Moreover, any glycemic control discrepancies between the NAP and UMPC sessions of the study could be entirely attributed to external factors – the behavioral and physiological variance of the study participants between the two sessions. When a clean experiment was made and NAP and UMPC were presented with identical input data as done throughout the duration of this study, the insulin dosing recommendations of the two algorithms were virtually identical. Further, the computational demands of NAP were 6-fold lower compared to the UMPC, without requiring third-party numerical solvers or libraries. While here this comparison was done on a computer (intelCore i5) and both 1.4 ms and 8.3 ms are exceedingly small, this difference would be of essence when the algorithm is scaled down to fit in an insulin pump. Thus, this pilot-feasibility study tested the concept of a neural-network encoding of a complex model-predictive AID control algorithm. In a randomized crossover trial, the neural net demonstrated similar performance to the original algorithm, at a fraction of the computational demands.³²

The second step was a further optimization of the neural network structure and size. This was completed in the summer of 2024 and IDE #G240236 was submitted to the FDA, with the objective to conduct a trial validating the optimized AIDANET (Automated insulin delivery as Adaptive Network) system during a 2-night house/hotel session and during 1 week at home. This IDE was approved on 10 Oct 2024 and the AIDANET trial is anticipated to be completed by the end of 2024 (NCT06633965). Participants use the AIDANET system in fully automated closed-loop (FCL) mode, with the exception of using their insulin-to-carbohydrate ratio as usual during 1 dinner in the house/hotel session of the study and 1 day at home and announcing eating initiation for 1 day at home. This study also includes a 1-week control period gathering data on glycemic control and insulin administration with the participants’ usual care therapy. Participants are randomized 1:1 to either Group A (control period prior to AIDANET use) or Group B (control period after AIDANET use).

Following Steps 1 and 2 described above, we developed a new version of the AIDANET bolus priming system (BPS) that uses reinforcement learning to determine pre-meal bolus amounts. Reinforcement learning (RL) is a branch of machine learning where an agent, like a neural network, learns to make decisions by interacting with its environment. Through trial and error, the agent receives feedback (rewards or penalties) for its actions, allowing it to refine its strategy over

time and maximize the total reward. By training our BPS using RL in an FDA-approved virtual environment, we developed a pre-meal bolus strategy optimized at the population level, meaning it works effectively for all patients. This updated BPS-RL is also able to analyze three days of glucose and insulin data to identify patterns and optimize the priming bolus, whereas the current BPS only uses the last 30 minutes of data. Moving forward, the RL-based system will allow for further personalization using patient-specific data in future research studies.

This protocol is the third step in the development of the next-generation AID algorithms that begin to use machine learning to adapt to the changing state of the person wearing the AID system. The goal of the protocol is to assess whether AIDANET plus reinforcement learning trained BPS (AIDANET+ BPS_RL) continues to provide safe and effective glycemia management as seen in prior studies.

(Note: Each of the previous referenced studies conducted at UVA were in compliance with 21 CFR parts 50, 56, and 812.)

Chapter 2: Study Synopsis

The new element of the AIDANET system to be tested in this study is the addition of a new BPS using machine learning to adapt and gradually improve the bolus-priming function of the system. It is anticipated that this is a step towards adaptive learning AID systems, potentially leading to completely FCL insulin delivery. All other elements of the AIDANET system described below, including the prototyping platform (the DiAs phone), the insulin pump, and the CGM sensor remain unchanged.

2.1 Study Objective

This study aims to demonstrate the safety and feasibility of the AIDANET+ BPS_RL algorithm, which replaces the BPS module in the previously tested AIDANET system with a new reinforcement learning trained BPS (BPS_RL).

2.2 Specific Aims and Hypotheses

Aim 1: To evaluate the performance (safety, efficacy) of AIDANET+ BPS_RL used as FCL.

Hypothesis: AIDANET+ BPS_RL use will result in equivalent or better Time in Range (TIR) than AIDANET (including current BPS) during two 18-hour hotel sessions (randomized crossover).

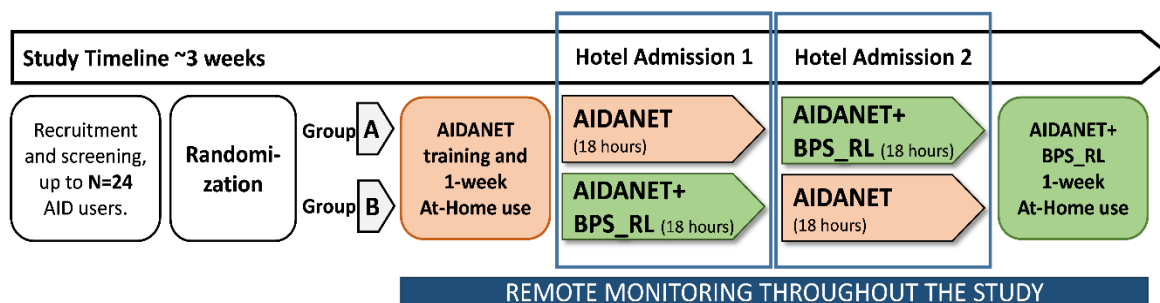

Aim 2: To evaluate the safety and efficacy of AIDANET+ BPS_RL at home.

Hypothesis: AIDANET+ BPS_RL use will result in equivalent or better TIR than AIDANET alone, during a week of At-Home use (repeated measures).

2.3 Study Design

This study is a randomized cross-over trial comparing AIDANET (including the current BPS) to AIDANET+ BPS_RL which includes the new BPS_RL (Figure 1). A week of AIDANET control at home will be followed by a two-night hotel session when participants will cross over from AIDANET to AIDANET+ BPS_RL and vice versa and will use new BPS_RL for a subsequent AIDANET+ BPS_RL week at home. For the majority of time, the participants will not announce meal ingestion to the system, thereby using the system in FCL mode of operation. However, the AIDANET system is designed to also work in hybrid closed-loop (HCL) mode with carbohydrate announcement, if requested by the user; thus, users will be allowed to enter carbohydrate amounts, which will be recorded by the system.

AIDANET+BPS_RL Study Timeline

Completion goal **N=16** subjects

Figure 1: Study Design

2.4 Study Hardware/Software

The study will involve using the previously tested AIDANET system, now equipped with a new BPS_RL designed to enable FCL and consisting of the following elements: the diabetes assistant (DiAs) prototyping platform, connected to a Tandem t:AP research insulin pump and a Dexcom G6 CGM.

2.5 Timing of Device Use

Following screening and randomization, all participants will be trained on the use of the study equipment and AIDANET algorithm. Participants will be connected to a Dexcom G6 sensor and the Tandem t:AP pump, which will be connected to the DiAs platform. AIDANET will be started on DiAs, and the participants will be trained how to use the Dexcom G6 sensor (if using Dexcom G7 in their AID system), the Tandem t:AP pump, and DiAs/AIDANET (see Table 1 and Figure 1). The t:AP pump will be programmed with back up parameters determined by the study investigator(s). Once started, the participants will have their glucose values managed through use of this system during the At-Home and hotel periods.

One-Week AIDANET: All participants will collect approximately one week of AIDANET baseline data. During this period, participants will generally use AIDANET in FCL mode. The DiAs Remote Monitoring will be on, supervised by study personnel.

Hotel Session: Participants will arrive at the hotel in the afternoon (prior to dinner). Those randomized to Group A will continue to use their AIDANET system. Those randomized to Group B will be switched to the AIDANET+BPS_RL system. Because AIDANET and AIDANET+BPS_RL have identical user interfaces and only the priming bolus calculation is changed “under the hood,” no additional training will be needed.

One-Week AIDANET+ BPS_RL: Participants will continue to use the Tandem t:AP pump, DiAs platform running the AIDANET+ BPS_RL, and Dexcom G6 CGM for glucose control for 7 days/6

243 nights during this period. The DiAs Remote Monitoring will be on, supervised by study personnel.
244 At the end of this period participants will return to their usual diabetes therapy.

245 **2.6 Meal Testing**

246 During the home study, participants will be instructed to consume their usual diet and will not be
247 required to record the timing of the meals. 2.3

248 **2.7 Study Devices Download**

249 Data from the study devices will be captured in real-time by the remote monitoring server for the
250 DiAs system. In addition, study devices will be downloaded at the end of the home visits.

251 **2.8 Study System Issues**

252 If the CGM signal becomes unavailable for more than 20 minutes consecutively, closed loop will
253 not operate to automatically adjust insulin delivery. If the CGM is not connected, the system will
254 revert to the usual open loop function of the pump and deliver insulin with the pre-programmed
255 dosing parameters. Resumption of closed-loop control will occur automatically once the CGM
256 signal is again available.

257 If the DiAs system is unable to maintain connectivity with the Tandem t:AP pump, the pump will
258 automatically revert to the pre-programmed dosing parameters after 30 minutes without any need
259 for interaction from the user.

Chapter 3: Study Screening

Visit 1

3.1 Clinical Site

The study will be performed at the University of Virginia. Screening procedures will be performed either virtually or on site, at a clinical research unit, or at the hotel.

3.2 Participant Recruitment and Enrollment

We will enroll up to 24 participants who have been diagnosed with T1D for at least one year. This enrollment number accounts for dropouts or screen failures that may occur. The goal is to complete a total of approximately 16 participants.

3.3 Informed Consent and Authorization Procedures

Before consent has been obtained, participants will be asked inclusion/exclusion criteria questions during pre-screening to determine study eligibility. Before completing any procedures or collecting any data that are not part of usual care, written informed consent will be obtained. Potential eligibility may be assessed as part of routine care examination.

A participant is considered enrolled when the informed consent forms have been signed by the participant and the study team.

Consenting procedures and documentation are defined in section 14.3.

After informed consent has been signed, a potential participant will be evaluated for study eligibility through review of medical history, performance of physical exam by a licensed health care professional, and other testing as needed per the I/E criteria.

3.4 Participant Inclusion Criteria

The participants must meet all of the following inclusion criteria in order to be eligible to participate in the study.

1. Age ≥ 18.0 years old at time of consent
2. Clinical diagnosis, based on investigator assessment, of Type 1 Diabetes for at least one year.
3. Having used an AID system equipped with Dexcom G6 or G7 CGM within the last three months (does not need to be continuous use if CGM was unavailable for instance).
4. Currently using insulin for at least six months.
5. Willingness to switch to use a commercially approved personal insulin (e.g., lispro or aspart, or biosimilar approved products) within the study pump as directed by the study team.
6. Has one or more supportive companions knowledgeable about emergency procedures for severe hypoglycemia and able to contact emergency services and study staff that either

lives with participant or located within approximately 30 minutes of participant and able to locate participant in the event of an emergency.

7. Participant not currently known to be pregnant or breastfeeding.
8. If participant capable of becoming pregnant, must agree to use a form of contraception to prevent pregnancy while a participant in the study (e.g. hormonal contraception, abstinence from heterosexual intercourse). A negative serum or urine pregnancy test will be required for all females of childbearing potential. Participants who become pregnant will be discontinued from the study. Also, participants who during the study develop and express the intention to become pregnant within the timespan of the study will be discontinued.
9. Willingness to use the study AIDANET system (CGM, pump, and phone) during the study period.
10. Willingness not to start any new non-insulin glucose-lowering agent during the course of the trial.
11. Willingness to participate in all study procedures including the house/hotel sessions.
12. Access to internet at home and willingness to upload data during the study as needed.
13. Investigator has confidence that the participant can successfully operate all study devices and is capable of adhering to the protocol.
14. Participant is proficient in reading and writing English.

3.5 Participant Exclusion Criteria

The participant must not have any exclusion criteria in order to be eligible to participate in the study.

1. Plans to start a new non-insulin glucose-lowering agent (e.g., GLP-1 receptor agonists, Symlin, DPP-4 inhibitors, sulfonylureas). Participants may be on a stable dose of such an agent for at least the past month.
2. Current use of an SGLT-2 or SGLT-1/2 inhibitor due to risk of euglycemic DKA.
3. Hemophilia or any other bleeding disorder.
4. History of severe hypoglycemic events with seizure or loss of consciousness in the last 12 months.
5. History of DKA event in the last 12 months.
6. Stage 4 chronic renal disease or currently on peritoneal or hemodialysis.
7. Currently being treated for adrenal insufficiency.
8. Currently being treated for a seizure disorder.
9. Hypothyroidism or hyperthyroidism is not adequately treated.
10. Use of oral or injectable steroids at the time of enrollment or within the last 4 weeks.
11. Planned surgery during the study period.
12. Known ongoing adhesive intolerance that is not well managed.
13. A condition, which in the opinion of the investigator or designee, would put the participant or study at risk.

14. Participation in another interventional trial at the time of enrollment.

15. Participant with a direct supervisor involved in the conduct of the trial.

3.6 Screening Procedures

The participant will be evaluated for study inclusion and exclusion eligibility after the informed consent forms have been signed by the participant and the study team. Screening procedures will last approximately 1-2 hours. The visit may occur in-person or remotely by HIPAA compliant video communication (e.g., Zoom, Webex). The following procedures may be performed/data collected/eligibility criteria checked and documented:

1. Inclusion and Exclusion criteria assessed
2. Demographics, including:
 - a. Date of birth
 - b. Gender
 - c. Race
 - d. Ethnicity
3. Medical History, including diabetes history
 - a. Duration of disease (number of years)
 - b. History of pump use
 - c. History of CGM use
 - d. Current treatment
 - e. Severe hypoglycemia history
 - f. DKA history
 - g. History of seizures
 - h. Loss of consciousness
4. Basal rates or basal insulin dosing
5. Carbohydrate ratios
6. Insulin sensitivity factors
7. Target glucose
8. Average daily insulin
9. Surgical history
10. Allergies
11. Concomitant medications
12. Physical Examination – A historical history and physical report within 6 months of screening appointments may be used but is not required for eligibility. If vitals are not available, may include self-reported values of all available vitals.
 - a. Weight
 - b. Height
 - c. Blood pressure
 - d. Temperature
 - e. Heart Rate

372 13. Screening Labs

- 373 a. Urine or serum pregnancy test for all women of childbearing potential (this test can
374 be done remotely with results sent to the study team)

375 A physical exam documented in the prior 12 months can suffice for the physical exam but will not
376 serve as an exclusion criterion if not available. Participants may self-report height, weight, blood
377 pressure, temperature, and heart rate; or these may be obtained by study staff at the enrollment
378 visit. An HbA1c value obtained in the previous one month may serve for the enrollment HbA1c
379 value.

380 If needed based on medical history, investigators may include baseline chemistry panel, liver
381 function tests, hematocrit, and thyroid stimulating hormone (lab results within one year of
382 screening appointment may be used). Any labs required may be obtained at a local laboratory (e.g.,
383 LabCorp, Quest) convenient to the participant. The study physician or physician designee will
384 have the discretion to repeat screening tests if applicable.

385 **3.7 Screen Failures / Participant Dropout**

386 If an exclusionary condition is identified, the study participant will be excluded from participation
387 with follow up and referral to their primary care physician as needed.

388 If the study participant is pregnant, the study physician will discuss the results of the blood test
389 with the participant and the participant will be asked to seek confirmation of the test and the
390 appropriate medical care.

391 Participants who screen-fail or dropout will be replaced if it occurs prior to the Hotel Admission.
392 Screen failed participants may be re-screened if their clinical situation changes as determined by
393 the study physician.

394 **3.8 Personal Equipment Downloads**

395 Up to 6 months of historical data from the participant's personal insulin pump, glucometer, or
396 continuous glucose monitor may be downloaded or recorded. Data will be obtained from the
397 participant's personal insulin pump, glucometer and CGM. This data may be obtained through the
398 commercial applications (e.g., Source, Tidepool, and Dexcom).

399 **3.9 Surveys**

400 Participants will be asked to complete the Demographic Data Survey, INSPIRE Survey, and
401 Technology Expectations Survey as described in section 8.2 prior to using AIDANET equipment.

402 **3.10 Other Considerations**

403 This study is not meant to find out if the participant has any other disease or problem. The study
404 leaders will alert the participant if any of the research results are important to the participant's
405 health during the study. The participant may have a copy of the screening tests to discuss with the
406 personal physician. If blood tests are completed, any blood left over will be thrown away. It will
407 not be stored for any future testing.

408 **3.11 Randomization**

409 Once eligibility is met and screening procedures are completed, the participant will proceed to
410 Randomization. Participants will be randomized 1:1 to one of two groups:

411 **GROUP A:** AIDANET followed by AIDANET+ BPS_RL during the hotel session

412 **GROUP B:** AIDANET+ BPS_RL followed by AIDANET during the hotel session

413 Randomization will occur via REDCap module.

Chapter 4: Study Devices & Training Visit

Visit 2

An HbA1c value for the participant will be collected prior to the start of the DiAs system. This can be a point-of-care value, lab value, or historical value from within 4 weeks of signing consent. Participants will be asked to place a new sensor 24-72 hours prior to the start of the Visit 2 to allow time for the CGM to warm-up prior to DiAs initialization. The study system is designed to enable full closed loop control and consists of the following elements: the diabetes assistant (DiAs) prototyping platform (smart phone), connected to a Tandem t:AP research insulin pump and a Dexcom G6 CGM.

Participants will come to the research center for initiation and training on the study device as described in Section 4.1. This will consist of 4-8 hours of training, tailored to the individual and include a supervised meal/snack. The participant will be asked to have an active Dexcom G6 sensor by the start of Visit 2; otherwise, a new CGM sensor will be placed. The study team will perform vital signs and inquire about any changes to the participant's medical history. Any changes to medical history will be communicated to the medical physician to ensure continued eligibility and participation.

The participant's CGM reading, and ketone concentration will be recorded. In the event that the participant's CGM reading is not between 80-250 mg/dL or ketone concentration is ≥ 0.6 mmol/L prior to initiation of the FCL system, the study physician may recommend additional insulin dosing according to the participants' usual doses. Study physician may elect to cancel participant's participation in the study if concerned about their medical safety. This participant will not be replaced.

The participant's home insulin pump will be discontinued, and the study insulin pump will be initiated. The study team will ensure the proper function of the CGM and insulin pump. The CGM used in the study is FDA-approved for the non-adjunctive measurement of blood glucose (i.e., the CGM reading can be used for insulin dosing decisions). The CGM readings will be the primary source of blood glucose values. There is no required protocol fingerstick blood glucose measurements at home other than at times of CGM calibration (if necessary) and if directed by the study team. Fingerstick blood glucose measurements may be taken whenever participants experience symptoms, if the CGM glucose is suspected to be erroneous, or any time the participant would like to be reassured. Glycemic Treatment Guidelines to be used during Visit 2 and the home portion are defined in section 6.6.

Any relevant contacts will be recorded on the CRF and summarized as appropriate (e.g. contact that is not a scheduling or supplies issue will not be recorded).

Participant will have a CGM between 80-250 mg/dL prior to leaving study site at conclusion of training session.

Remote monitoring will be in place during the At-Home Periods as detailed in section 7.2.

4.1 Insulin Pump and DiAs

4.1.1 Equipment Description.

A study insulin pump and DiAs will be provided to all participants at this training visit.

The t:AP research insulin pump will be programmed with the participants' usual pump parameters (basal insulin rate, insulin to carbohydrate ratio, and insulin correction factor) as determined by the study physician. These parameters serve as backup-only settings for the system in open loop mode, and do not determine behavior of the AIDANET algorithm. The bolus priming system (BPS) profile determines the maximum fraction of total daily insulin (TDI) that can be injected by the BPS depending on the time of day (e.g., 8% between 06:00 and 10:00). The BPS profile is a setting on DiAs which can be modified by the provider to impact performance of the AIDANET algorithm. The study physician may alter the BPS profile during the hotel session and At-Home portions of the study to optimize participant safety with the experimental system.

4.1.2 Equipment Training

The purpose of this training visit is to introduce the study system to the participants. Training on the DiAs and study pump may begin when the AIDANET system has been put in place. The participants will be trained in the basic functionality (e.g., bolus menu and infusion set change menu) for the study pump. For the Tandem pump training, a checklist is available on-line with relevant sections applicable to the study pump will be covered. Insulin parameters will be determined by the investigator(s) and programmed into their study insulin pump and confirmed by two research staff. Participants will then switch to the study insulin pump. The participant's personal pump will be removed. The investigator may elect to use an existing personal pump infusion site at their discretion at the start of the study. The participant will be instructed on charging the pump, menu navigation, bolus procedures, and infusion site changes. The DiAs training includes information on charging the phone, maintaining connectivity, menu navigation including bolus procedures and TCR adjustments.

Data-driven optimization of pump or system settings can occur at any time, particularly if the participant contacts the study physician due to concerns about their pump settings due to recurring hypo- or hyperglycemia.

4.2 Continuous Glucose Monitor

4.2.1 Equipment Description

The study CGM will include the Dexcom G6 transmitter and sensor. Participants may elect to wear their personal Dexcom G6 CGM equipment throughout the study period. If currently wearing a G7 CGM model, the participant will be provided with G6 CGM supplies. These sensors may be worn for up to 10 days of continuous wear. The G6 transmitter may be worn for 3 months.

4.2.2 Equipment Training

A study CGM will be provided to all participants as needed prior to or at the training session at Visit 2. Participants using the Dexcom G6 may continue their personal CGM during the study

session. The participants will be provided with CGM equipment and instructed to use CGM on a daily basis. If the participant has prior use of the G6, retraining will be specific to the individual. The study team may elect to have less frequent CGM users watch the Dexcom online training videos (<https://www.dexcom.com/training-videos>) to assist in the training session. Study staff training may include review of the study CGM in real-time to make management decisions and how to review the data after an upload for retrospective review. Study staff will specifically identify how alarms are set using the app and the frequency that these alarms will repeat.

For participants not using the Dexcom G6, the participants will be observed placing the sensor and will learn/review how to access the CGM trace via the Dexcom G6 commercial app (prior to the hotel session) and via the DiAs phone (during the hotel session). The participants will be asked to perform fingerstick blood glucose measurements (if needed) in accordance with the labelling of the study CGM device. An electronic copy of the CGM user's guide will be provided for these participants to read. The study team will be sure that the participants will leave the training session knowing how to properly use the CGM. The study team will be available for any questions.

The study team will ask participants to share their data to the study Dexcom clinical account. This requires a one-time confirmation of data sharing between either the participant's personal Dexcom account or the study Dexcom account and the study clinical account. Participants are identified in the study clinical account by their assigned participant number. The participant does not need to provide the study team with their own login information at any point in this process. The Dexcom clinical account allows the study team to remotely assess and download data as needed. Data sharing between the personal Dexcom account or study Dexcom account and the clinical account can be ended at any time by the participant.

During the study, participants will have the option of using their personal smartphone or receive a study smartphone to use in order to collect the data from the devices. They may also use their own Dexcom G6 or G7 CGM. If the participant elects to use a personal device, the Dexcom app will be downloaded to their phone in order to monitor the participant's CGM values and alerts in real-time may be used prior to initiating DiAs.

4.3 Blood Glucose Meter and Strips

A study glucometer will be provided to all participants to record any blood glucose levels measured during the study. Participants will be advised to use the study glucometer when experiencing a low or high glucose values as defined in the Glycemic Treatment Guidelines. The Dexcom CGM will be calibrated, if needed, using the study glucometer and test strips in accordance with the manufacturer's labeling.

If the study glucometer provides an app, the study team will request that the app be downloaded to the participant's personal phone. The app will permit continued visibility of blood glucose values to the participant and permit the study team to download the data without returning the glucometer at the end of the study.

525 **4.4 Ketone Meter and Strips**

526 Blood ketone levels will be measured during the hotel session and At-Home Period of the study
527 with either the Abbott Precision Xtra Meter or the Ketomojo Meters and ketone test strips in
528 accordance with the manufacturer's labeling. Urine ketone strips may be provided to the
529 participant for the At-Home Period. The glucometer component of either ketone meters will not
530 be used.

531 **4.5 Study Devices Accountability Procedures**

532 Device serial numbers will be recorded, and use of equipment will be tracked.

Chapter 5: AIDANET At-Home Period

5.1 AIDANET use at home

Visit 3

Participants will use the study equipment with the AIDANET algorithm for 7 days/6 nights. Participants will be instructed to follow their normal routine involving diet, exercise, and insulin administration during this week.

Participants using their personal Dexcom CGM will share their CGM download data with the study team at the completion of this week.

Remote monitoring will be in place during this At-Home Period as detailed in section 7.2. Participants will be advised to call the study team if they have any questions or concerns.

Approximately 24-48 hours after initiating the system, the study team will contact the participant via phone/email/text/video to assess adverse events, adverse device effects, and device issues. If the participant chooses, this visit can occur at the clinical site. The study team will verify the following information:

1. Review system use
2. Inquire about any changes to the participant's medical history
3. Inquire about any changes to the participant's medication
4. Review of CGM data
5. Review of hypoglycemic events
6. Review of hyperglycemic events

Any other relevant contacts during the week will be recorded on the CRF and summarized as appropriate (e.g. contact that is not a scheduling or supplies issue will not be recorded).

5.2 Pre-Hotel Check-In Visit

Visit 4

All participants will be contacted by the study team approximately 24-48 hours prior to the hotel admission. The study team will verify the following information:

- a. Inquire about any changes to the participant's medical history
- b. Study equipment (e.g., CGM) has been initiated. A new CGM sensor will be placed approximately 24-72 hours prior to the hotel session for proper warm-up.
- c. Verify with participant that the goal CGM reading at time of arrival is less than 200 mg/dL; this may require contact with the study physician prior to arrival on the day of the study visit.
- d. Bring personal insulin and glucagon to hotel session.

Should any concerns regarding medical history, pump information, or unforeseen issues arise, the admission will be cancelled for that participant at the discretion of the investigator.

Chapter 6: Supervised Hotel Fully Closed-Loop Period

Visit 5 and 6

6.1 Hotel Session

The study will be performed for about 40 hours, including two 18-hour experiment sessions, at a local hotel/rental house. Participants will use the AIDANET system in the hotel setting from the afternoon/evening of Day 1 through discharge in the morning of Day 3. They will then continue to use the system for the second At-Home Period of the study.

6.2 Qualifications and Role of the Staff

There will be at least two study staff present at all times at the study site, at least one of whom will be clinical staff (e.g., nurse, physician, nurse practitioner, physician assistant). There will be a physician at the hotel or nearby on call during the study at all times. In addition, at least one senior engineer will be on call during the entire hotel session. Participants will be remotely monitored by at least one study team member (maybe trained staff, nurse, physician, NP, or PA) using a web-based remote monitoring system that has been previously established for DiAs. The web-based remote monitoring system will display real-time insulin delivery, CGM and other system information to allow for patient safety monitoring. In addition, study team members will be trained in all protocol and Glycemic Treatment Guideline procedures. The closed-loop system will be managed by the participant with study-staff supervision if needed. Glucagon for the emergency treatment of hypoglycemia will be available on-site. Participants will be instructed to bring their own rescue glucagon, though each site will also bring emergency rescue glucagon to the study.

6.3 Hotel Session Check-In

Participants will arrive at the hotel on the first day of the hotel session. The study team will perform vital signs and inquire about any changes to the participant's medical history. Any changes to medical history will be communicated to the medical physician to ensure continued eligibility and participation.

The participant's CGM reading, and ketone concentration will be recorded. In the event that the participant's CGM reading is not between 80-250 mg/dL or ketone concentration is ≥ 0.6 mmol/L prior to initiation of the FCL system, the study physician may recommend additional insulin dosing according to the participants' usual doses. Study physician may elect to cancel participant's participation in the hotel admission if concerned about their medical safety. This participant will not be replaced.

The participant's home insulin pump will be discontinued, and the study insulin pump will be initiated. The study team will ensure the proper function of the CGM and insulin pump. The CGM used in the study is FDA-approved for the non-adjunctive measurement of blood glucose (i.e., the CGM reading can be used for insulin dosing decisions). The CGM readings will be the primary source of blood glucose values. There is no required protocol fingerstick blood glucose measurements other than at times of CGM calibration (if necessary) and if directed by the study team. Fingerstick blood glucose measurements may be taken whenever participants experience

symptoms, if the CGM glucose is suspected to be erroneous, or any time the participant would like to be reassured. Glycemic Treatment Guidelines to be used during the hotel admission are defined in section 6.6.

6.4 Study Meals

Participants will eat approximately 3 freely chosen unannounced meals per day during the supervised hotel session. Study staff will record the time the meal was eaten so that analysis of the AIDANET algorithm's performance around the mealtime may be conducted. Snacks with carbohydrates will not be allowed unless for the treatment of low blood sugars. Non-carbohydrate snacks may be allowed throughout the hotel session per investigator discretion. Blood glucose levels will be followed via CGM with interventions for glucose extremes as per the Glycemic Treatment Guidelines.

6.5 Hotel Session Activities

Participants will also be free to engage in additional low-intensity activity (i.e., walking) during the hotel admission. Study staff will accompany participants if they leave the house/hotel.

6.6 Glycemic Treatment Guidelines

Hypo- and Hyperglycemia occurring while using the AIDANET system will be managed per the following protocol during both the hotel session and At-Home Period of the trial. Glycemic Treatment Guidelines will be available for staff use during the study sessions and will be provided to participants for the At-Home Period of the study.

6.6.1 Hypoglycemia

- a. If CGM falls below 70 mg/dL at any time, confirm <70mg/dL CGM readings and potential hypoglycemia symptoms with a fingerstick blood glucose. If blood glucose confirms <70mg/dL CGM reading, hypoglycemia will be treated with oral glucose of approximately 5-15 g. Participants will be encouraged to wait 15 min prior to giving a second glucose treatment. These fingerstick checks will be performed during the hotel stay and during the home portion if the participant chooses to do so. During the hotel stay we will also recheck a fingerstick blood glucose before retreatment.
- b. If a participant experiences any symptoms of hypoglycemia (e.g., shakiness, dizziness, sweating, pallor, clumsiness, difficulty paying attention, or tingling around the mouth), then the participant should treat with oral glucose of 5-15 g. Participants will be encouraged to wait 15 min prior to giving a second glucose treatment. During the hotel portion of the study, a fingerstick blood glucose will be assessed before such treatment for symptoms and before any re-treatment.
- c. If a participant displays any signs of neuroglycopenia (e.g., lethargy, disorientation, confusion, or inappropriate behavior) or severe hypoglycemia (e.g., hypoglycemic seizure, loss of consciousness, inability to properly consume treatment)

hypoglycemia will be treated with either oral glucose or glucagon. The patient will be discharged from the study. The participant should consult with study physician to discuss next steps for broader evaluation of symptoms unrelated to hypoglycemia.

6.6.2 Hyperglycemia

If CGM value is >300 mg/dL for 2 hours or >400 mg/dL at any time, check fingerstick BG and ketone level every 60±15 minutes. If unexplained hyperglycemia, evaluate the integrity of the insulin site, consider changing the site and providing a correction bolus as recommended by the bolus calculator. If insulin is given subcutaneous injection rather than through the DiAs, closed-loop control should be suspended for up to four hours unless directed by a study clinician.

6.7 Hotel Session Discharge

Discharge will occur after lunch on Day 3. CGM must be between 80-250 mg/dL with ketones ≤0.6 mmol/L prior to discharge. The study team will answer any remaining questions that the participant may have about using the system at home. After discharge, participants will proceed to the Remote Monitored At-Home Period of the study.

6.8 Other Issues

The participant will be instructed to notify study staff if they experience any issues with the study devices. During the hotel phase, staff will provide hands-on support and troubleshooting training for any device issues. If subcutaneous insulin is needed, the participant will turn off closed-loop mode as instructed by study staff. During the At-Home Period, participants will be instructed to contact the staff on-call in the event of subcutaneous insulin need. If insulin is delivered by any means other than the study pump, the participant will be instructed to turn off closed-loop mode for approximately four hours. This timeframe can be adjusted by the study physician.

The participant will also be asked to alert the study clinical staff for technical issues with the Tandem research pump and/or the DiAs system, including use of the study pump and study CGM (open loop mode) during periods of component disconnections or technical difficulties.

Glucagon will be available at the hotel once the investigational system is in place. All participants will confirm that they have rescue glucagon available at home for the At-Home Period.

Chapter 7: AIDANET+BPS_RL At-Home Period

Visit 7

7.1 AIDANET+BPS_RL use at home

Upon discharge on Day 3 of the hotel period, participants will begin a 7-day/6-night Remote Monitored At-Home stage of the study. Participants will continue to wear the FCL research system as initiated during the hotel period. Participants will be instructed to eat approximately 3 freely chosen meals per day without announcing them to the system. Participants will be instructed to participate in their usual level of physical activity. Participants will complete the study after lunch on overall study Day 9 (Day 7 of the home portion), at which point they will return to use of their usual diabetes care.

Approximately 24-48 hours after initiating the system, the study team will contact the participant via phone/email/text/video to assess adverse events, adverse device effects, and device issues. If the participant chooses, this visit can occur at the clinical site. The study team will verify the following information:

1. Review system use
2. Inquire about any changes to the participant's medical history
3. Inquire about any changes to the participant's medication
4. Review of CGM data
5. Review of hypoglycemic events
6. Review of hyperglycemic events

Any other relevant contacts during the week will be recorded on the CRF and summarized as appropriate (e.g. contact that is not a scheduling or supplies issue will not be recorded).

7.2 Remote Monitoring

All participants will continue to be remote monitored during the two At-Home Periods of the study, AIDANET and AIDANET + BPS_RL, using the connection between DiAs and DiAs Web Monitoring (DWM) platform at UVA. Study staff may review the AID system data on the DWM platform as needed; in addition, at each site, a licensed medical provider (MD, PA, NP, RN, CDCES) will receive the following automated alerts from the DWM (automated notification system, ANS):

1. CGM > 300 mg/dL for 1 hour.
2. CGM < 70 mg/dL for 20 minutes.
3. CGM < 55 mg/dL at any point.
4. No sensor data for > 1 hour.

The provider on call will contact study participants (e.g., call, text, or video chat) and/or their companion for any of the above CGM alerts which are not resolved within a timely manner. Participants will be asked to manage glycemic extremes per the hyper- hypoglycemia safety protocol.

707 Contact (e.g., phone, text, email, etc.) with the study team will occur as needed. Any relevant
708 contacts will be recorded on the CRF and summarized as appropriate (e.g. contact that is not a
709 scheduling or supplies issue will not be recorded).

710 **7.3 Surveys**

711 All participants will complete the INSPIRE and Technology Acceptance survey at the conclusion
712 of the At-Home study.

713 **7.4 Post-Study Check-In**

714 **Visit 8**

715 Approximately 24-48 hours after the hotel session, the study team will contact the participant via
716 phone/email/text/video to:

- 717 • Ask about any changes to the participant's medical history and medication.
- 718 • Review any hypoglycemic events that are less than 60 mg/dL.
- 719 • Review any hyperglycemic events that are more than 300 mg/dL .
- 720 • Verify that questions have been answered. The study physician or designee will be
721 available for any questions related to insulin adjustments/parameters.

722 The study team may contact the participant for issues related to data collection and equipment
723 issues.

724 **7.5 Early Termination Visit (If Applicable)**

725 Participants will be asked to attend the Post-Study Check-In Visit (visit 8) in the event of a
726 withdrawal or early termination.

727 **7.6 Unscheduled Visits**

728 Participants may have unscheduled visits during the study period if required for additional device
729 training or other unanticipated needs per the study investigator discretion.

Chapter 8: Testing Procedures

8.1 Laboratory and Point of Care Testing

8.1.1 HbA1c

A blood sample (either capillary or venous draw) will be obtained at screening to obtain a baseline Hemoglobin A1c level. A blood test obtained within 4 weeks prior to enrollment may be used. HbA1c level may be measured by the study team using the DCA2000, a comparable point of care device, at time of screening. Labs may be obtained at a local laboratory (e.g., LabCorp, Quest) convenient to the participant.

8.1.2 Pregnancy Test

A serum or urine pregnancy test will be required for participants capable of becoming pregnant at screening. Test must be negative to participate in the study.

8.2 Questionnaires

8.2.1 Demographic Data Survey

Research in diabetes technology has revealed significant disparities in minoritized population's representation in clinical trials and access to devices that improve diabetes outcomes. Collection of detailed demographic data regarding participants in technology trials has become essential. This includes data on race/ethnicity, income levels and insurance status, as well as education and other variables that describe the study population.

The Demographic Data Survey will be electronically administered once eligibility has been met. The below information will be gathered for all participants.

- a. Age
- b. Gender
- c. Race
- d. Ethnicity
- e. Marital status
- f. Level of education
- g. Employment status
- h. Household income
- i. Health insurance status
- j. Monthly insulin costs and co-payments

8.2.2 INSPIRE Questionnaire

The self-administered INSPIRE (INSulin Dosing Systems: Perceptions, Ideas, Reflections and Expectations) questionnaire have been developed to determine the psychosocial impact of AID

763 systems in a range of relevant factors specific to youth with T1D (8-17 years of age) and adults
764 with T1D, as well as parents/caregivers of youth with T1D, and partners of adults with T1D.

765 The questionnaire will be administered prior to the start of the investigational device and at the
766 conclusion of the study.

767 **8.2.3 Technology Expectation/Acceptance Survey**

768 Participants will complete a Technology Expectation/Acceptance Survey which includes questions
769 about attitudes, feelings, and behaviors related to the technology used in this study.

770 The questionnaire will be administered prior to the start of the investigational device and at the
771 conclusion of the At-Home Period.

Chapter 9: Risks Associated with the Clinical Trial

9.1 Potential Risks and Benefits of the Investigational Device

Risks and Benefits are detailed below. Loss of confidentiality is a potential risk; however, data are handled to minimize this risk. Hypoglycemia, hyperglycemia and ketone formation are always a risk in participants with T1D and participants will be monitored for these symptoms.

9.1.1 Venipuncture Risks

A hollow needle/plastic tube will be placed in the arm for taking blood samples. Blood draws can cause some common reactions like pain, bruising, or redness at the sampling site. Less common reactions include bleeding from the sampling site, formation of a small blood clot or swelling of the vein and surrounding tissues, and fainting.

9.1.2 Fingerstick Risks

About 1 drop of blood will be removed by fingerstick for measuring blood sugars and sometimes HbA1c or other tests. This is a standard method used to obtain blood for routine hospital laboratory tests. Pain is common at the time of lancing. In about 1 in 10 cases, a small amount of bleeding under the skin will produce a bruise. A small scar may persist for several weeks. The risk of local infection is less than 1 in 1000. This should not be a significant contributor to risks in this study as finger sticks are part of the usual care for people with diabetes.

9.1.3 Subcutaneous Catheter Risks (CGM)

Participants using the CGM will be at minimal risk for developing a local skin infection at the site of the sensor needle placement. If a needle is left under the skin for more than 24 hours, it is possible to get an infection where it goes into the skin, with swelling, redness and pain. There may be bleeding where the catheter is put in and bleeding under the skin causes a bruise (1 in 10 risk).

Study staff should verbally alert the participant that on rare occasions, the CGM may break and leave a small portion of the sensor under the skin that may cause redness, swelling, or pain at the insertion site. The participant should be further instructed to notify the study coordinator immediately if this occurs.

9.1.4 Risks of Hypoglycemia

As with any person having T1D and using insulin, there is always a risk of having low blood sugar (hypoglycemia). The frequency of hypoglycemia should be no more and possibly less than it would be as part of daily living. Symptoms of hypoglycemia can include sweating, jitteriness, and not feeling well. Just as at home, there is the possibility of fainting or seizures (convulsions) and that for a few days the participant may not be as aware of symptoms of hypoglycemia. A CGM functioning poorly and significantly over-reading glucose values could lead to inappropriate insulin delivery.

9.1.5 Risks of Hyperglycemia

Hyperglycemia and ketonemia could occur if insulin delivery is attenuated or suspended for an extended period or if the pump or infusion set is not working properly. A CGM functioning poorly and significantly under-reading glucose values could lead to inappropriate suspension of insulin delivery.

9.1.6 Risks of Device Reuse

Participant will be informed that FDA or relevant national authorities have approved the insulin pump, CGM, glucometer and ketone meter for individual use and that by using them among multiple patients, bloodborne pathogens (i.e. Hepatitis B) may be spread through the use of multiple users.

The study CGM system is labelled for single use only. The sensor (the component of the system that enters the skin) will be individual use only. The transmitter and receiver may be reused during the study after the study team cleans the device using a hospital-approved cleaning procedure. The transmitter is attached to the sensor but does not enter the skin and the receiver, if used, is a handheld device.

CGM cleaning instructions are provided in the Dexcom G4 Platinum (Professional) Cleaning and Disinfection manual (current edition) and a similar approach will be applied for the CGMs used in this study.

The study insulin pumps are labelled for single-patient use. During the study, this device may be reused after the study team cleans the device with a hospital-approved cleaning procedure. All infusion set equipment will be single patient use only (infusion set insertion kits, tubing, cartridges etc.)

The study-provided blood glucose meter will be returned to the study participant at the conclusion of the study after the study team has confirmed data collection. The study team will use cleaning procedures if it is necessary to be in physical contact with the equipment to download the device. The study team will clean the ketone meter per manufacturer directions.

9.1.7 Device Cleaning Instructions

Members of the study team will clean the study equipment after use as noted in these instructions. CGM cleaning instructions are provided in the Dexcom G4 PLATINUM (Professional) Cleaning and Disinfection manual (current edition). The transmitter should be cleaned with Clorox Healthcare® Bleach Germicidal Cleaner or any disinfectant product in a spray bottle containing a bleach solution of 6500 parts per million with the EPA registration number 56392-7. The transmitter will be submerged in this solution and then placed on an absorbent wipe or clean surface. Two sprays will be dispensed from the Clorox cleaner onto each side of the transmitter. A nylon brush will be used to scrub the transmitter on all sides for 30 seconds. The transmitter will be placed in the Clorox Cleaner solution for one minute. The transmitter is then rinsed under flowing tap water for ten seconds. The transmitter will then be disinfected using a disinfectant product with EPA registration number 56392-7 using similar procedures as the cleaning process.

Per the pump manufacturer, the insulin pump will be cleaned with a damp lint-free cloth. Use of household or industrial cleaners, solvents, bleach, scouring pads, chemicals, or sharp instruments are prohibited. The pump should never be submerged in water. If needed, use only a very mild detergent, such as a bit of liquid soap with warm water. A soft towel will be used to dry the pump.

The glucometer is cleaned and disinfected with two separate Super Sani-Cloths (EPA number 9480-4). The entire surface will be cleaned, making sure the surface stays wet for 2 minutes. This step is repeated with a clean cloth for disinfecting the device.

The Precision Xtra User's Guide suggests that healthcare professionals use 10% bleach, 70% alcohol or 10% ammonia to clean the device.

Equipment that touches intact skin will be cleaned with ethyl or isopropyl alcohol (70-90%), quaternary ammonium germicidal detergent (i.e. Cavicide, EPA number 46781) or household bleach. The contact time on the surface depends on the method used to clean the equipment. Cavicide requires three minutes on the surface of the equipment. Clorox Germicidal Bleach Wipes require two minutes on the equipment. The surface should remain wet (i.e. slightly damp) with the disinfectant to be considered effective though not wet enough to leave drops of liquid.

In the event a manufacturer updates cleaning procedures for their device, the study team will adhere to the most current recommendations.

There is the risk of blood sampling collection and contamination from sampling techniques. Hand washing with either soap & water or waterless hand sanitizer will be used prior to caring for the study subject. Gloves will be worn during blood sample collection and processing. Medical personnel will continue to practice hygiene for the subject's protection (i.e. hand washing, changing gloves frequently, disposing needles properly). Gloves will be removed, and hands washed or sanitized prior to leaving and upon return to the subject's room. Soiled linen will be changed to minimize the transfer of pathogenic organisms.

9.1.8 Hb1Ac Risk

An NGSP Point of Care analyzer (i.e. DCA Vantage Analyzer) will be utilized at the research site to obtain the subject's HbA1c level.

9.1.9 Other Risks

Some participants may develop skin irritation or allergic reactions to the adhesives used to secure the CGM, or to secure the insulin infusion sets for the continuous subcutaneous insulin infusion. If these reactions occur, different adhesives or "under-taping" (such as with IV 3000, Tegaderm, etc.) will be tried, sites will be rotated frequently, and a mild topical steroid cream or other medication may be required.

Whenever the skin is broken there is the possibility of an infection. The CGM and pump infusion sites are inserted under the skin. It is possible that any part that is inserted under the skin may cause an infection. These occur very infrequently, but, if an infection was to occur, oral and/or topical antibiotics can be used. The risk of skin problems could be greater if you use a sensor for longer

than it is supposed to be used. Therefore, participants will be carefully instructed about proper use of the sensor.

Data downloaded from the CGM, insulin pump, glucometer, and ketone meter will be collected for the study as measures of diabetes self-management behaviors. Some people may be uncomfortable with the researchers' having such detailed information about their daily diabetes habits.

9.1.10 Known Potential Benefits

It is anticipated that this protocol will yield increased knowledge about using an automated closed-loop system with anticipatory action to control glucose levels. The individual participant may not benefit from study participation.

9.1.11 Risk Assessment

Based on the facts that (1) adults and adolescents with diabetes experience mild hypoglycemia and hyperglycemia frequently as a consequence of the disease and its management, (2) the study intervention involves periodic automated insulin dosing that may increase the likelihood of hypoglycemia, and periodic automated attenuation of insulin delivery that may increase the likelihood of hyperglycemia, (3) mitigations are in place, and have been tested in prior studies using the investigational device system in the home setting, that limit the likelihood of excessive insulin dosing or prolonged withdrawal of insulin, and (4) rapid reversal of hypoglycemia and hyperglycemia can be achieved, it is the assessment of the investigators that this protocol falls under DHHS 46.405 which is a minor increase over minimal risk. In addition, it is the belief of the investigators that this study also presents prospects of direct benefit to the participants and general benefit to others with diabetes.

9.2 General Considerations

The study is being conducted in compliance with the policies described in the study policies document, with the ethical principles that have their origin in the Declaration of Helsinki, with the protocol described herein, and with the standards of Good Clinical Practice (GCP).

Whenever possible, data will be directly collected in electronic case report forms, which will be considered the source data.

The protocol is considered a significant risk device study, due to the fact that the closed loop system is experimental. Therefore, an investigational device exemption (IDE) from the U.S. Food and Drug Administration (FDA) is required to conduct the study.

912 **Chapter 10: Adverse Events, Device Issues, and Stopping Rules**

913 **10.1 Definitions**

914 **10.1.1 Adverse Events (AE)**

915 Any untoward medical occurrence in a study participant, irrespective of the relationship between
916 the adverse event and the device(s) under investigation (section 10.2) for reportable adverse events
917 for this protocol.

918 Positive pregnancy test will not be considered an adverse event.

919 **10.1.2 Serious Adverse Event (SAE)**

920 Any untoward medical occurrence that:

- 921 • Results in death.
- 922 • Is life-threatening; (a non-life-threatening event which, had it been more severe, might
923 have become life-threatening, is not necessarily considered a serious adverse event).
- 924 • Requires inpatient hospitalization or prolongation of existing hospitalization.
- 925 • Results in persistent or significant disability/incapacity or substantial disruption of the
926 ability to conduct normal life functions (life threatening).
- 927 • Is a congenital anomaly or birth defect.
- 928 • Is considered a significant medical event by the investigator based on medical judgment
929 (e.g., may jeopardize the participant or may require medical/surgical intervention to
930 prevent one of the outcomes listed above).

931 **10.1.3 Unanticipated Adverse Device Effect (UADE)**

932 Any serious adverse effect on health or safety or any life-threatening problem or death caused by,
933 or associated with, a device, if that effect, problem, or death was not previously identified in nature,
934 severity, or degree of incidence in the investigational plan or application (including a
935 supplementary plan or application), or any other unanticipated serious problem associated with a
936 device that relates to the rights, safety, or welfare of participants (21 CFR 812.3(s)).

937 **10.1.4 Adverse Device Effect (ADE)**

938 Any untoward medical occurrence in a study participant which the device may have caused or to
939 which the device may have contributed.

940 **10.1.5 Device Complaints and Malfunctions**

941 A device complication or complaint is something that happens to a device or related to device
942 performance, whereas an adverse event happens to a participant. A device complaint may occur
943 independently from an AE, or along with an AE. An AE may occur without a device complaint or
944 there may be an AE related to a device complaint. A device malfunction is any failure of a device
945 to meet its performance specifications or otherwise perform as intended. Performance
946 specifications include all claims made in the labeling for the device. The intended performance of
947 a device refers to the intended use for which the device is labeled or marketed. (21 CFR 803.3).

10.2 Reportable Events

For this protocol, a reportable adverse event includes any untoward medical occurrence that meets one of the following criteria:

- A serious adverse event as defined in section 10.1.2.
- An Adverse Device Effect as defined in section 10.1.4, unless excluded from reporting in section 10.7.
- An Adverse Event as defined in section 10.1.1 occurring in association with a study procedure.
- An AE as defined in section 10.1.1 which leads to discontinuation of a study device for 4 or more hours during the hotel phase and 12 or more hours during the at home phase.
- Hypoglycemia meeting the definition of severe hypoglycemia as defined in section 10.2.1
- Diabetic ketoacidosis (DKA) as defined in section 10.2.2 or in the absence of DKA, a hyperglycemic or ketosis event meeting the criteria defined below.

Hypoglycemia and hyperglycemia not meeting the criteria below will not be recorded as adverse events unless associated with an Adverse Device Effect. Skin reactions from sensor placement are only reportable if severe and/or required treatment.

10.2.1 Hypoglycemia Event

Hypoglycemia not associated with an Adverse Device Effect is only reportable as an adverse event when the following definition for severe hypoglycemia is met:

- The event required assistance of another person due to altered consciousness, and required another person to actively administer carbohydrate, glucagon, or other resuscitative actions.
- Impaired cognitively to the point that he/she was unable to treat himself/herself, was unable to verbalize his/ her needs, was incoherent, disoriented, and/or combative, or experienced seizure or coma. These episodes may be associated with sufficient neuroglycopenia to induce seizure or coma.
- If plasma glucose measurements are not available during such an event, neurological recovery attributable to the restoration of plasma glucose to normal is considered sufficient evidence that the event was induced by a low plasma glucose concentration.

10.2.2 Hyperglycemia Events/Diabetes Ketoacidosis

Hyperglycemia not associated with an Adverse Device Effect is only reportable as an adverse event when one of the following four criteria is met:

- The event involved DKA, as defined by the Diabetes Control and Complications Trial (DCCT) and described below.
- Evaluation or treatment was obtained at a health care provider facility for an acute event involving hyperglycemia or ketosis.
- Blood ketone level ≥ 1.5 mmol/L and communication occurred with a health care provider at the time of the event.
- Blood ketone level ≥ 3.0 mmol/L, even if there was no communication with a health care provider.

Hyperglycemic events are classified as DKA if the following are present:

- Symptoms such as polyuria, polydipsia, nausea, or vomiting.
- Serum ketones ≥ 1.5 mmol/L or large/moderate urine ketones.
- Either arterial blood pH < 7.30 or venous pH < 7.24 or serum bicarbonate < 15 .
- Treatment provided in a health care facility.

All reportable Adverse Events—whether volunteered by the participant, discovered by study personnel during questioning, or detected through physical examination, laboratory test, or other means—will be reported on an adverse event form online. Each adverse event form is reviewed by the Study Physician to verify the coding and the reporting that is required.

10.3 Relationship of Adverse Event to Study Device

The Study Physician will assess the relationship of any adverse event to be related or unrelated by determining if there is a reasonable possibility that the adverse event may have been caused by the study device or study procedure. To ensure consistency of AE causality assessments, the study investigator should apply the following general guideline when determining whether an adverse event is related:

Unrelated: The AE is clearly not related to a study device/procedure and a likely alternative etiology exists such as an underlying disease, environmental or toxic factors or other therapy.

Unlikely Related: The AE does not follow a reasonable temporal sequence during or after use of study device or a study procedure and a more likely alternative etiology exists such as an underlying disease, environmental or toxic factors, or other therapy.

Possibly Related: The AE occurred in a reasonable time during or after use of study device or a study procedure; but could be related to another factor such as an underlying disease, environmental or toxic factors, or other therapy; and there is a possible, though weak, scientific basis for establishing a causal association between the AE and the study drug/device.

Probably Related: The AE occurred in a reasonable time during or after use of study device or a study procedure; is unlikely to be related to another factor such as an underlying disease, environmental or toxic factors, or other therapy; and there is a plausible, though not strong, scientific basis for establishing a causal association between the AE and the study drug/device.

Definitely Related: The AE occurred in a reasonable time during or after use of study device or a study procedure; cannot be explained by another factor such as an underlying disease, environmental or toxic factors, or therapy; and there is a strong scientific basis for establishing a causal association between the AE and the study drug/device.

10.4 Severity (Intensity) of Adverse Event

The severity (intensity) of an adverse event will be rated on a three-point scale: (1) mild, (2) moderate, or (3) severe. It is emphasized that the term severe is a measure of intensity: thus, a severe adverse event is not necessarily serious. For example, itching for several days may be rated as severe, but may not be clinically serious.

-
- MILD: Usually transient, requires no special treatment, and does not interfere with the participant's daily activities.
 - MODERATE: Usually causes a low level of inconvenience or concern to the participant and may interfere with daily activities but is usually ameliorated by simple therapeutic measures.
 - SEVERE: Interrupts a participant's usual daily activities and generally requires systemic drug therapy or other treatment.

10.5 Expectedness

For a serious adverse event that is considered possibly related to study device, the Study Physician will classify the event as unexpected if the nature, severity, or frequency of the event is not consistent with the risk information previously described in the approved labelling of the study system.

10.6 Outcome of Adverse Events

The outcome of each reportable adverse event will be classified by the investigator as follows:

- RECOVERED/RESOLVED WITH NO SEQUELAE – The participant recovered from the AE/SAE without sequelae. Record the AE/SAE stop date.
- RECOVERED/RESOLVED WITH SEQUELAE – The event persisted and stabilized without change in the event anticipated. Record the AE/SAE stop date.
- FATAL – A fatal outcome is defined as the SAE that resulted in death. Only the event that was the cause of death should be reported as fatal. AEs/SAEs that were ongoing at the time of death; however, were not the cause of death, will be recorded as “resolved” at the time of death.
- NOT RECOVERED/NOT RESOLVED (ONGOING) – An ongoing AE/SAE is defined as the event was ongoing with an undetermined outcome. An ongoing outcome will require follow-up by the site in order to determine the final outcome of the AE/SAE. The outcome of an ongoing event at the time of death that was not the cause of death, will be updated and recorded as “resolved” with the date of death recorded as the stop date.
- ONGOING (MEDICALLY STABLE) – AE/SAE is ongoing, but medically stable. For example, a chronic condition where no further change is expected.
- UNKNOWN – An unknown outcome is defined as an inability to access the participant or the participant's records to determine the outcome (for example, a participant that was lost to follow-up).

If any reported adverse events are ongoing when a participant completes the study (or withdraws), adverse events classified as UADEs or related SAEs will be followed until they are either resolved, or have no prospect of improvement or change, even after the participant has completed all applicable study visits/contacts. For all other adverse events, data collection will end at the time the participant completes the study, unless further follow up is requested by the Study Physician. Note: participants should continue to receive appropriate medical care for an adverse event after their participation in the study ends.

If a participant is lost to follow up and participant outcome cannot be determined, outcome classification will be the last known outcome.

10.7 Reportable Device Issues

All UADEs, ADEs, device complaints, and device malfunctions will be reported irrespective of whether an adverse event occurred, except in the following circumstances.

The following device issues are anticipated and will not be reported but will report as an Adverse Event if the criteria for AE reporting described above are met:

- Component disconnections
- CGM sensors lasting fewer than the number of days expected per CGM labeling
- CGM tape adherence issues
- Pump infusion set occlusion not leading to ketosis
- Battery lifespan deficiency due to inadequate charging or extensive wireless communication
- Intermittent device component disconnections/communication failures not leading to system replacement
- Device issues clearly addressed in the user guide manual that do not require additional troubleshooting
- Skin reactions from CGM sensor placement or pump infusion set placement that do not meet criteria for AE reporting

10.8 Timing of Event Reporting

- UADEs must be reported within 10 working days to the FDA after the sponsor first receives notice of the adverse effect.
- Other reportable adverse events, device malfunctions (with or without an adverse event) and device complaints should be reported promptly, but there is no formal required reporting period.
- The IDE Sponsor will investigate the UADE and if indicated, report the results of the investigation to the IRBs and FDA within 10 working days of the study team becoming aware of the UADE per 21CFR 812.46(b) (2).
- The Study Physician will determine if the UADE presents an unreasonable risk to participants. If so, the Study Physician must ensure that all investigations, or parts of investigations presenting that risk, are terminated as soon as possible but no later than 5 working days after the Study Physician makes this determination and no later than 15 working days after first receipt notice of the UADE.
- In the case of a device system component malfunction (e.g. pump, CGM, control algorithm), information will be forwarded to the responsible manufacturer by the study personnel.

10.9 Stopping Criteria

10.9.1 Participant Discontinuation

A participant will be discontinued if any of the following occur:

- The Study Physician believes it is unsafe for the participant to continue the intervention. This could be due to the development of a new medical condition or worsening of an

-
- 1105 existing condition; or participant behavior contrary to the indications for use of the device
1106 that imposes on the participant's safety
- 1107 • The participant requests that the treatment be stopped
 - 1108 • Two distinct episodes of DKA
 - 1109 • Two distinct severe hypoglycemia events as defined in section 10.2.1.
 - 1110 • Two events of any kind: severe hypoglycemia or DKA

1111 **10.9.2 Suspending/Stopping Overall Study**

1112 In the case of an unanticipated system malfunction resulting in a severe hypoglycemia or severe
1113 hyperglycemia event (as defined in section 10.2.2), use of the study device system will be
1114 suspended while the problem is diagnosed.

1115 In the event that two distinct episodes of DKA or two distinct severe hypoglycemia events as
1116 defined in section 10.2.1 occur, the overall study would be suspended while the underlying
1117 conditions are determined.

1118 In addition, study activities could be similarly suspended if the manufacturer of any constituent
1119 study device requires stoppage of device use for safety reasons (e.g., product recall). The affected
1120 study activities may resume if the underlying problem can be corrected by a protocol or system
1121 modification that will not invalidate the results obtained prior to suspension. As previously noted,
1122 the Study Physician will review all adverse events and adverse device events that are reported
1123 during the study. The Study Physician may request suspension of study activities or stoppage of
1124 the study if deemed necessary based on the totality of safety data available.

1125 **10.10 Definition of a Data Breach**

1126 A data breach is defined in the HITECH Act (43 USC 17932) as an unauthorized acquisition,
1127 access, or use of protected health information (PHI) that compromises the security or privacy of
1128 such information.

1129 **Chapter 11: Miscellaneous Considerations**

1130 **11.1 Prohibited Medications, Treatments, and Procedures**

1131 Participants using glulisine at the time of enrollment will be asked to contact their personal
1132 physician to change their prescribed personal insulin to lispro or aspart for the duration of the trial.

1133 The study devices (study insulin pump, study CGM) must be removed before Magnetic Resonance
1134 Imaging (MRI), Computed Tomography (CT) or diathermy treatment. Participants may continue
1135 in the trial after temporarily discontinuing use if requiring one of the treatments above.

1136 **11.2 Participant Withdrawal**

1137 Participation in the study is voluntary. Participant may withdraw at any time. For participants who
1138 do withdraw from the study, the study team will determine if their data will be used in analysis.

1139 **11.3 Confidentiality**

1140 For security and confidentiality purposes, subjects will be assigned an identifier that will be used
1141 instead of their name. Protected health information gathered for this study may be shared with the
1142 third-party collaborators. De-identified subject information may also be provided to collaborators
1143 involved in the study after the appropriate research agreement has been executed.

1144 **11.4 Lost to Follow Up**

1145 If a participant is lost to follow up and participant outcome cannot be determined, outcome
1146 classification will be the last known outcome/contact with the participant. A participant will be
1147 considered lost to follow-up after three attempted contacts that do not result in any communication
1148 from the participant. A certified letter may be sent as the fourth and final attempt to communicate
1149 with the participant.

Chapter 12: Statistical Consideration

12.1 Design and Randomization

This pilot study aims to demonstrate the safety and feasibility of the AIDANET+BPS_RL algorithm, which replaces with a new BPS_RL the bolus priming module of our AIDANET system described in IDE #G240236, which was approved by the FDA on October 10, 2024.

As presented in Figure 1, this study is a randomized cross-over trial comparing AIDANET to AIDANET+BPS_RL, which includes the new BPS_RL. A week of AIDANET control at home will be followed by a two-night hotel stay where participants will cross over from AIDANET to AIDANET+BPS_RL and vice versa and will learn how to operate the new BPS_RL for a subsequent AIDANET+BPS_RL week at home. The participants are not expected or encouraged to announce meals to the system, thus the system will run in fully-automated closed loop (FCL) mode.

Eligible participants will be randomized to two groups, A and B, which differ only by the order of administration of AIDANET or AIDANET+BPS_RL during the hotel section of the study. The remaining procedures are identical for both groups A and B. The randomization list will use a sequence of computer-generated pseudorandom Bernoulli trials and will aim to balance groups by baseline HbA1c (Figure 1).

12.2 Sample Size

We use pilot trials to introduce new technologies, test system component interoperability, and support regulatory approval of larger subsequent studies. Depending on the traceability of the system to previous established technology or components, the pilots can range from a small 5-person 3-day trial, such as the one we used to enable the pivotal trial of Control-IQ, to a multi-center test of pump configurations. This study is directly traceable to the studies described in IDE #G230052 (Neural Net Artificial Pancreas, NAP) and IDE #G240236 (AIDANET), in terms of algorithm functionality – as noted above, the new element is the replacement of the AIDANET built in bolus priming with a new BPS_RL. Thus, based on our experience, we estimate that the completion of N=15 (and recruitment of up to 20) AID system users, will be feasible in terms of first regulatory approval of the new BPS_RL, and sufficient to assess the effect size of the transitions between the existing AIDANET and the new AIDANET+BPS_RL.

The overall aim is to achieve effect size $f = 0.2$ on the primary outcome described below. If this effect size is confirmed, then a subsequent larger study, which is planned within the scope of the NIH/NIDDK Grant RO1 DK 133148 supporting this pilot, will need a sample size of N=50 completed participants to establish superiority of the new AIDANET+BPS_RL over its current version.

12.3 Outcome Measures

The primary outcome will be the CGM-measured time in range (TIR, 70-180 mg/dL) during the 18-hour hotel sessions on AIDANET or AIDANET+BPS_RL (Figure 1). The time periods begin at 6 PM and end at noon on the next day, thereby covering two meals – dinner and breakfast. These

time periods are expected to reflect well any differences, e.g., potential TIR improvement, that can be attributed to the new BPS_RL.

Secondary outcomes from the 18-hour Hotel Sessions of the study (see Figure 1):

Descriptive glycemic analyses for certain efficacy measures recommended by the International Consensus on TIR, to which we contributed, will be tabulated for each subject based on CGM data, including:

- percentage of readings in other ranges, including time below range (TBR, < 70 mg/dl), time above range (TAR, > 180 mg/dl) and time in tight range 70-140 mg/dl;
- mean glucose; glucose variability measured by coefficient of variation;
- percentage of readings <54 mg/dl (i.e., level 2 hypoglycemia)
- percentage of readings >250 and >300 mg/dl (i.e., level 2 hyperglycemia).

Secondary outcomes from the 1-week Home Sessions of the study (see Figure 1):

All CGM-based glycemic metrics computed during the Hotel sessions of the study will be computed during the Home sessions as well. *The last 3 days of each week at home on AIDANET or AIDANET+BPS_RL will be used for the analyses described below.*

We will also observe, record, and tabulate any system errors that would inform us whether system fixes would be needed prior to deployment in a subsequent larger study. We will tabulate technical performance metrics including:

- Malfunctions requiring study team contact and other reported device issues;
- Percent time in closed-loop and any other relevant operational modes;
- Rate of relevant AIDANET+BPS_RL failure events and alarms per 24 hours;

The technical performance, errors, and glycemic analyses will be also split by time of the day: daytime vs. night-time.

12.4 Planned Analysis

The primary statistical effect of interest is the change in TIR resulting from the transition from AIDANET to AIDANET+BPS_RL and vice versa. Thus, the analysis will involve use of repeated measures General Linear Model (GLM), with emphasis on the interaction corresponding to the crossover design. The analysis will use covariates, e.g., baseline HbA1c, gender, and TIR within the first week on AIDANET alone (see Figure 1).

All secondary outcomes will be similarly analyzed. In particular, the CGM-based metrics of the last 3 days on AIDANET will be compared to the last 3 days on AIDANET+BPS_RL using repeated measures CLM with covariates as described above. If the distribution of an outcome is not suited for GLM (e.g., profound skewness, or atom at boundary), we will perform paired Wilcoxon signed rank test (and lose the capacity to use covariates) to test difference in the median instead of the mean; this is expected for time < 54 mg/dl and possibly time >250 and 300 mg/dL.

We do not plan to correct for multiple comparisons. We do not expect substantial missing values in this supervised study, but if more than 20% of the data for the primary outcome is missing, we will consider switching to mixed models that handle missing data better.

12.5 Safety Analyses

We will assess for the system's functionality, including the ability of the system to run its code without errors (delivering insulin safely), as well as its ability to avoid low BGs <70 mg/dL.

12.6 Criteria for Success

The success criteria will include no critical system errors and the following performance criteria, which factor in likely inter-day variability for each participant and are consistent with the recommendations of the International Consensus on TIR:

- Positive difference in TIR between AIDANET+BPS_RL and AIDANET, e.g. TIR on AIDANET+BPS_RL greater than TIR on AIDANET, regardless of p-value;
- Difference in TBR between AIDANET+BPS_RL and AIDANET < 3 percentage points;
- Positive difference in TAR between AIDANET+BPS_RL and AIDANET.

Formal power analysis is not applicable to this pilot study – with this sample size a statistically significant result is not expected (Power less than 50%). The point of the study is to show feasibility of the new BPS and assess whether effect size $f=0.2$ is achievable in a subsequent study.

12.7 CGM data treatment

- Saturated CGM values “High” and “Low” will be replaced by 401mg/dL and 39mg/dL respectively.
- CGM data during recorded occlusion event will be removed from analysis as follows: any measurement less than 2h before or after the time of record will be removed.
- CGM data following a pump/DiAs communication interruption >1h but less than 2h will be removed.

12.8 Baseline Descriptive Statistics

Baseline demographic and clinical characteristics of the cohort of all randomized participants will be summarized in a table using summary statistics appropriate to the distribution of each variable. The following descriptive statistics will be displayed overall and by treatment group:

- i. Age
- ii. HbA1c
- iii. Gender
- iv. Race/ethnicity
- v. Diabetes duration
- vi. BMI
- vii. Total Daily Insulin.

1258 **Chapter 13: Data Collection and Monitoring**

1259 **13.1 Case Report Forms and Device Data**

1260 The study data are collected through a combination of case report forms (electronic and paper) and
1261 electronic device data files obtained from the software and individual hardware components.
1262 These electronic device files and electronic CRFs are considered the primary source
1263 documentation.

1264 When data are directly collected in electronic case report forms, this will be considered the source
1265 data. Records will be maintained in accordance with ICH E6 and institutional regulatory
1266 requirements for the protection of confidentiality of participants.

1267 **13.2 Study Records Retention**

1268 Study documents should be retained for a minimum of 2 years after the last approval of a marketing
1269 application in an ICH region and until there are no pending or contemplated marketing applications
1270 in an ICH region or until at least 2 years have elapsed since the formal discontinuation of clinical
1271 development of the investigational product. These documents should be retained for a longer
1272 period, however, if required by local regulations. No records will be destroyed without the written
1273 consent of the sponsor, if applicable. It is the responsibility of the sponsor to inform the investigator
1274 when these documents no longer need to be retained.

1275 **13.3 Protocol Deviations**

1276 A protocol deviation is any noncompliance with the clinical trial protocol, Good Clinical Practices
1277 (GCP), or procedure requirements. The noncompliance may be either on the part of the participant,
1278 the investigator, or the study site staff. As a result of deviations, corrective actions may be
1279 developed by the site and implemented as appropriate. Major deviations will be reported to the
1280 IRB-HSR within 7 calendar days of when the study team becomes aware of the event.

Chapter 14: Ethics/Protection of Human Participants

14.1 Ethics Standard

The investigator will ensure that this study is conducted in full conformity with Regulations for the Protection of Human Participants of Research codified in 45 CFR Part 46, 21 CFR Part 50, 21 CFR Part 56, and/or the ICH E6.

14.2 Institutional Review Boards

The protocol, informed consent form(s), recruitment materials, and all participant materials will be submitted to the IRB for review and approval. Approval of both the protocol and the consent form must be obtained before any participant is enrolled. Any amendment to the protocol will require review and approval by the IRB before the changes are implemented to the study. All changes to the consent form will be IRB approved; a determination will be made regarding whether previously consented participants need to be re-consented.

14.3 Informed Consent Process

Informed consent is a process that is initiated prior to an individual's agreement to participate in the study and continues throughout the individual's study participation. The potential participant will be provided with a short overview of the study including its study goals, study procedures, and study timeline. If the potential participant remains interested, they will be asked permission to review inclusion/exclusion criteria to assess if they are eligible to participate in the study. If permission is granted, the study team will review the Inclusion/Exclusion criteria (section 3.4 and 3.5). If eligible, the study team member will provide a copy of the informed consent form (e.g., in person, email, fax, or mail) to the potential participant for their review. Potential participants may also elect to review the informed consent form prior to discussing pre-screening questions.

The potential participant will be provided with ample time to read and review the consent form. After their review, the study team will discuss the study at length in a phone call/HIPAA compliant telecommunication method for consenting that is not face to face. All participants will receive verbal explanation in terms suited to their comprehension of the purposes, procedures, and potential risks of the study and of their rights as research participants. Extensive discussion of risks and possible benefits of participation will be provided. The potential participant will be given an opportunity to ask the study team questions or may speak directly with the study physician. The potential participant's understanding of the information presented in the process of consent will be assessed by asking open-ended questions.

The consent form may be signed electronically for both in-person and telecommunication screening visits. Note: For potential participants who are not able to sign an electronic consent form, in-person, email, fax, or mail will be alternatives used to obtain a signed consent. A HIPAA compliant video conferencing tool (e.g., Zoom, WebEx) will be utilized during the consenting process of the telecommunication screening visit to facilitate the FDA Part 11 compliant process of verification of reviewing two forms of identification if signing electronically off site.

1318 Participants can download a PDF copy of the signed consent and automatically receive a PDF via
1319 email from REDCap after the form is completed. CRCs also could download, print, and mail a
1320 paper copy for each participant. Study procedures may begin once the consent has been signed by
1321 the participant and a member of the study team.

1322 The rights and welfare of the participants will be protected by emphasizing to them that the quality
1323 of their medical care will not be adversely affected if they decline to participate in this study.

1324 **14.4 Participant and Data Confidentiality**

1325 The IRB-HSR Post Approval Monitoring (PAM) auditors, representatives of the IRB, or device
1326 company supplying study product may inspect documents and records required to be maintained
1327 by the investigator, including but not limited to, medical records (office, clinic, or hospital) for the
1328 participants in this study.

1329 The study participant's contact information will be securely stored at the clinical site for internal
1330 use during the study. At the end of the study, all records will continue to be kept in a secure location
1331 for as long a period as dictated by local IRB and institutional regulations. The study data entry and
1332 study management systems used by research staff will be secure and password protected. At the
1333 end of the study, all study databases will be archived at the UVA CDT.
