1 Introduction

1.1 Trial information

This is a 2-year, multinational, open-label, two-arm parallel, randomised trial with glycaemic target in subjects with T2DM inadequately controlled with OAD(s).
Inadequately controlled T2DM will be defined as an HbA1c level of 7.0-11.0% (53-97 mmol/mol), both inclusive. A total of 1000 subjects will be randomised in a 1:1 manner using a centralised allocation via interactive web response system.

Subjects will be randomised to receive either once daily (QD) IDegLira or IGlar in combination with OAD(s) at randomisation. Dipeptidyl peptidase-4 (DPP-4) inhibitors and glinides must be discontinued at randomisation.

1.2 Scope of the statistical analysis plan

This Statistical Analysis Plan (SAP) is based on Final Protocol version 4.0 (16-Dec-2016).

The scope of this SAP is to update the sensitivity analyses for the primary endpoint. Furthermore, some errors have been corrected and descriptive statistics that did not address the scientific objectives have been omitted. For further details on the changes see section 3.

2 Statistical considerations

Novo Nordisk will analyse and report data from all sites together.

All analyses of efficacy and safety endpoints will be based on the full analysis set (FAS).

All efficacy endpoints and PRO endpoints will be summarised using the FAS and safety endpoints will be summarised using the safety analysis set (SAS).

The impact of protocol deviations and outliers may be investigated further in sensitivity analyses if deemed relevant.

Unless otherwise specified, all continuous measurements will be summarised descriptively at each visit by treatment using observed data. Endpoints that are analysed untransformed and endpoints that are not formally analysed are summarised by the arithmetic mean, standard deviation, median, and minimum and maximum value. Endpoints that are analysed log-transformed are summarized with the geometric mean and coefficient of variation. For measurements over time, mean values will be plotted to explore the trajectory over time. Observed data will be used as the basis for plotting data if not otherwise specified. Change from baseline plots will be based on Least Square Means and SEs estimated from the mixed model for repeated measurement (MMRM). For

endpoints that are analysed log-transformed, the geometric mean values will be plotted. All descriptive summaries and plots will be based on on-treatment data unless otherwise specified.

Only endpoints derived after 26 and 104 weeks of treatment will be analysed statistically.

Subjects withdrawing from the trial or discontinuing treatment will contribute to the primary analysis as needing rescue therapy from the time of withdrawal/discontinuation.

For secondary endpoints, the expected percentage of missing data after 26 weeks of treatment is around 5%. Due to the nature of the trial design, the expected percentage of missing data after 104 weeks of treatment is 45% and 55% for IDegLira and IGlar respectively.

If an assessment has been made both at screening and randomisation, and if not otherwise specified, the value from the randomisation visit will be used as the baseline value. If the value measured at the randomisation visit is missing and the assessment also has been made at screening, then the screening value will be used as the baseline value.

Laboratory values below the lower limit of quantification (LLOQ) will be set to ½LLOQ.

A MMRM with an unstructured covariance matrix, with testing performed at week 26 and 104 will be applied for secondary continuous endpoints. The model includes treatment, visit, HbA_{1c} group, pre-trial diabetes medication and region as fixed factors and the corresponding baseline value as a covariate. Interactions between visit and all factors and the covariate are also to be included in the model.

The factor "baseline HbA_{1c} group" is a dichotomised baseline HbA_{1c} variable with 2 categories: HbA_{1c} <8.5% or HbA_{1c} ≥8.5%.

The factor "previous OAD treatment" has 2 levels: OAD(s) + sulphonylurea or OAD(s).

The factor "region" has 5 levels: Europe (Norway, Israel, Russia, Turkey, Italy, UK, Slovakia, Hungary, Czech Republic and Poland), North America (US), South America (Mexico, Brazil and Argentina), Africa (South Africa), and Asia (India).

In the following, this model will be referred to as the standard MMRM model. This analysis will estimate the difference in change from baseline in the endpoint between IDegLira and IGlar assuming that subjects remain on trial product until week 26 and 104, respectively. In this model it is assumed that data are missing at random which is a reasonable assumption since most missing data will arise from subjects withdrawing due to inadequate glucose control as observed at the time of withdrawal.

Presentation of results from a statistical analysis will include the estimated mean treatment effects (Least Square Means) for absolute values and change from baseline. In addition, estimated mean

treatment difference (or ratio) will be presented together with the two-sided 95% confidence interval and corresponding two-sided p-value.

2.1 Sample size calculation

Sample size calculations are described in the protocol section 17.1 and will not further be described here.

2.2 Definition of analysis sets

The following analysis sets are defined in accordance with the ICH-E9 guidance:

Full Analysis Set (FAS): includes all randomised subjects. In exceptional cases, subjects may be eliminated from the FAS. In such cases the elimination will be justified and documented.

The statistical evaluation of the FAS will follow the intention-to-treat principle and subjects will contribute to the evaluation "as randomised".

Safety Analysis Set (SAS): includes all subjects receiving at least 1 dose of the investigational product or comparator. Subjects in the safety set will contribute to the evaluation "as treated".

Randomised subjects who are lost to follow up and where no exposure information of the investigational product or comparators is available after randomisation will be handled as unexposed.

Before data are released for statistical analysis, a review of all data will take place to identify protocol deviations that could potentially affect the results. Any decision to exclude any subject or observation from the statistical analysis is the joint responsibility of the members of the study group. The subjects or observations to be excluded and the reason(s) for their exclusion will be documented and signed by all parties. The documentation will be stored together with the remaining trial documentation.

2.3 Primary endpoint

The following endpoint will be assessed up to 104 weeks. Time from randomisation to inadequate glycaemic control and need for treatment intensification defined as an HbA_{1c} ≥7% at 2 consecutive visits from week 26 (including week 26, if HbA_{1c} was ≥ to 7% at week 12).

Subjects withdrawing from the trial or discontinuing treatment will contribute to the primary analysis as needing rescue therapy from the time of withdrawal/discontinuation. The data will inherently be interval censored, since HbA_{1c} is only measured at the scheduled visits while subjects may reach an HbA_{1c} ≥7.0% at any time between 2 visits (including week 26 if HbA1c was ≥ to 7% at week 12).

The primary endpoint will be analysed using a stratified log-rank test where treatment, baseline HbA_{1c} group and previous OAD treatment will be included as strata in the model.

The variable "baseline HbA_{1c} group" is a dichotomised baseline HbA_{1c} variable with 2 categories: $HbA_{1c} < 8.5\%$ or $HbA_{1c} \geq 8.5\%$.

The variable "previous OAD treatment" is a categorical variable with 2 categories: OAD(s) + sulphonylurea or OAD(s).

Formally, let D be the hazard ratio for time to treatment intensification. The null-hypothesis of no treatment difference will be tested against the alternative hypothesis as given by

H0: D =1 against HA: D ≠1

Kaplan-Meier curves by treatment arm and strata from the model will be presented.

Sensitivity analysis

Two sensitivity analyses will be carried out taking the interval censored nature of the data into account.

The possible failure times will be viewed as continuous variables which can only be observed to lie in the interval between the visit when treatment failure is established and the previous scheduled visit.

The first sensitivity analysis will take the interval censored nature of the data into account by using a proportional hazards regression model for interval censored data with piecewise constant baseline hazard. Baseline HbA_{1c} group and previous OAD treatment will be included in the model by stratification, while treatment and region will be included as factors in the model. The estimated treatment hazard ratio (IDegLira vs. IGlar) will be presented together with the two-sided 95% confidence interval and corresponding two-sided p-value.

In the second sensitivity analysis, the time to inadequate glycaemic control and need for treatment intensification will be compared between the IDegLira arm and the IGlar arm using a two-sided nonparametric test at a 5% significance level. The test will be a generalised log rank test for interval censored failure time data. The analysis will not be based on any model assumptions such as proportional hazards.

2.4 Secondary endpoints

2.4.1 Supportive secondary endpoints

2.4.1.1 Efficacy endpoints

Time from randomisation to HbA_{1c} > 6.5% at 2 consecutive visits from week 26.
Time from randomisation to HbA_{1c} > 6.5% at 2 consecutive visits from week 26 (including week 26 if HbA_{1c} was > 6.5% at week 12) will be analysed and presented in the same way as the primary endpoint.

HbA_{1c}
Change from baseline in HbA_{1c} after 26 weeks of treatment will be analysed using the standard MMRM model. Mean curves by time of treatment discontinuation will be plotted.

Body weight
Change from baseline in body weight after 26 and 104 weeks of treatment will be analysed using the standard MMRM model.

Insulin dose after 26 and 104 weeks of treatment
The actual insulin dose will be summarised descriptively according to regimen as dose in units, and units/kg. The actual daily insulin dose will be analysed using the standard MMRM model.

HbA_{1c} responder after 26 and 104 weeks of treatment (yes/no)
Two dichotomous endpoints (responder/non-responder) will be defined based on whether a subject has met a specific target level after 26 and 104 weeks of treatment:

- HbA_{1c} target < 7.0%
- HbA_{1c} target ≤ 6.5%

Analysis of each of the four responder endpoints will be based on a logistic regression model with treatment, HbA_{1c} group, previous OAD treatment and region as fixed factors and baseline HbA_{1c} value as a covariate. Subjects withdrawing from the trial or discontinuing treatment will be imputed as being non-responder from time of withdrawal/discontinuation in line with the evaluation of the primary endpoint.

HbA_{1c} responder endpoints without weight gain
Responder for HbA_{1c} without weight gain after 26 and 104 weeks of treatment will be defined as HbA_{1c}<7.0% or ≤6.5% and change in body weight from baseline ≤ 0. Analysis of each of the 2 responder endpoints will be based on a logistic regression model with treatment, HbA_{1c} group, previous OAD treatment and region as fixed factors and baseline HbA_{1c} and baseline body weight as covariates. Subjects withdrawing from the trial or discontinuing treatment will be imputed as being non-responder from time of withdrawal/discontinuation in line with the evaluation of the primary endpoint.

HbA_{1c} responder endpoints without treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes

Responder for HbA_{1c} without treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes after 26 and 104 weeks of treatment will be defined as $HbA_{1c} < 7.0\%$ or $\leq 6.5\%$ and without treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes during the last 12 weeks of each treatment period. Analysis of each of the 2 responder endpoints will be based on a logistic regression model with treatment, HbA_{1c} group, previous OAD treatment and region as fixed factors and baseline HbA_{1c} values as a covariate. Subjects withdrawing from the trial or discontinuing treatment will be imputed as being non-responder from time of withdrawal/discontinuation in line with the evaluation of the primary endpoint.

HbA_{1c} responder endpoints without treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes and without weight gain

Responder for HbA_{1c} without treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes and without weight gain after 26 and 104 weeks of treatment will be defined as $HbA_{1c} < 7.0\%$ or $\leq 6.5\%$ without treatment-emergent severe or BG confirmed symptomatic during the last 12 weeks of each treatment period, and change in body weight from baseline ≤ 0. Analysis of each of the 2 responder endpoints will be based on a logistic regression model with treatment, HbA_{1c} group, previous OAD treatment and region as fixed factors and baseline HbA_{1c} values and baseline body weight as covariates. Subjects withdrawing from the trial or discontinuing treatment will be imputed as being non-responder from time of withdrawal/discontinuation in line with the evaluation of the primary endpoint.

Fasting plasma glucose

Change from baseline in FPG after 26 and 104 weeks of treatment will be analysed using the standard MMRM model.

9-point profile

The following 6 endpoints from the 9-point SMPG profile will be defined:

- 9-point profile (individual points in the profile)
- Mean of the 9-point profile, defined as the area under the profile (calculated using the trapezoidal method) divided by the measurement time
- Prandial plasma glucose increments (from before meal to 90 min after for breakfast, lunch and dinner). The mean increment over all meals will be derived as the mean of all available meal increments

A linear mixed effect model will be fitted to the 9-point profile data at week 26 and week 104. The model will include treatment, region, time (within 9-point profile), the interaction between treatment and time, the interaction between region and time as fixed factors, and subject as random

effect, where measurements within subjects will be assumed correlated using a compound symmetry covariance matrix.

Change from baseline in mean of the 9-point profile and prandial increment endpoints will be analysed separately using the standard MMRM model.

Blood pressure (systolic and diastolic)
Change from baseline in systolic and diastolic blood pressure will be analysed separately using the standard MMRM model.

Fasting C-peptide and fasting human insulin
These endpoints will be analysed separately using the standard MMRM model. In these statistical analyses, the endpoint will be log-transformed and so will the corresponding baseline covariate.

Fasting lipid profile
Cholesterol, LDL cholesterol, HDL cholesterol, VLDL cholesterol, triglycerides and free fatty acids will be analysed separately using the standard MMRM model. In these statistical analyses, the endpoint will be log-transformed and so will the corresponding baseline covariate.

2.4.1.2 Safety endpoints

Adverse events
AEs will be coded using the most recent version of the Medical Dictionary for Regulatory Activities.

A TEAE is defined as an event that has onset date on or after the 1st day of exposure to trial product and no later than 7 days after the last day of trial product. If the event has onset date before the 1st day of exposure on trial product and increases in severity during the treatment period and until 7 days after the last drug date, then this event should also be considered as a TEAE. MACEs are considered treatment-emergent until 30 calendar days after the last day of trial product.

TEAEs are summarised descriptively, whereas non-TEAEs are presented in listings. TEAE data will be displayed in terms of the number of subjects with at least 1 event (N), the percentage of subjects with at least 1 event (%), the number of events (E) and the event rate per 100 years of exposure (R).

Summaries of TEAEs and of serious TEAEs will be presented as an overview including all AEs, serious AEs, number of deaths, AEs by severity, AEs by relation to treatment and AEs of special interest including AEs leading to treatment discontinuation or withdrawal.

Furthermore summary tables based on system organ class and preferred terms are made for:
- All TEAEs
- Serious TEAEs

- TEAEs possibly or probably related to trial product
- Severe, moderate and mild TEAEs
- TEAEs reported by safety areas of interest
- TEAEs with preferred term that are experienced by at least 5% (1%) of the subjects in any treatment arm or by at least 5% (1%) of all subjects

A listing for non-TEAEs with onset date before the first day of exposure to trial product will be presented. A listing will also be presented for non-TEAEs collected after the treatment-emergent period according to the definition of TEAE. All summaries will be prepared for TEAEs during 26 and 104 weeks of treatment separately.

Additional summaries will be displayed for MACEs collected between visit 13 and visit 13A for subjects who discontinue trial product prematurely.

Hypoglycaemic events
Data on treatment-emergent hypoglycaemic episodes are presented in terms of the number of subjects with at least 1 event (N), the percentage of subjects with at least 1 event (%), the number of events (E) and the event rate per 100 years (R).

Separate summaries are made by severity considering all severe or BG confirmed symptomatic hypoglycaemic episodes, nocturnal severe or BG confirmed symptomatic hypoglycaemic episodes and the ADA classification of hypoglycaemia. All summaries will be prepared for episodes during 26 and 104 weeks of treatment separately.

A negative binomial model with a log-link function and the logarithm of the time period in which a hypoglycaemic episode is considered treatment-emergent as offset will be used to analyse the number of treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes during 26 and 104 weeks of treatment. The model will further include treatment, HbA_{1c} group, previous OAD treatment and region as fixed factors.

Number of treatment-emergent nocturnal severe or BG confirmed symptomatic hypoglycaemic episodes during 26 and 104 weeks of treatment will be analysed using the same model as used for the treatment-emergent severe or BG confirmed symptomatic hypoglycaemic episodes.

Clinical evaluation (eye examination, ECG and urine albumin/creatinine ratio)
Eye examination, ECG findings and urine albumin/creatinine ratio will be summarised descriptively, including:

- Summaries for each visit
- Change from baseline after 104 weeks of treatment

Pulse
Change from baseline in pulse will be analysed using the standard MMRM model.

Laboratory assessments (Biochemistry, Haematology and Calcitonin)
All laboratory parameters will be summarised descriptively.

The following tables will be presented:
- Shift tables from baseline to after 26 and 104 weeks of treatment
- Proportion of subjects with measurements outside reference range by treatment and week

For each laboratory parameter, individual values outside the reference ranges (abnormal values) will be listed. Summaries by visit will be based on data from scheduled visits. If a blood re-sample related to a specific visit is made, the first value will be used.

For lipase and amylase the following rule applies in the evaluation of the result:
- If the amylase or lipase baseline (at screening) value is > 3x upper normal range the information will be regarded as medical history for that subject

2.5 Health economics endpoints

The following questionnaires will be used to compare PROs between treatments:
- SF-36v2
- TRIM-D

For each questionnaire, the summary scores will be summarised descriptively by visit and the change from baseline in score will be analysed separately using the standard MMRM model.

3 Changes to the statistical analyses planned in the protocol

Corrections have been made to the parameterization of the baseline hazard in the first sensitivity analyses for the primary analysis.

Models for fasting C-peptide and fasting human insulin have been updated to be analysed as log-transformed endpoints as this was erroneously left out in the protocol.

The model fitted to the 9-point profile data has been simplified so that profile data from previous visits are disregarded in the modelling of the week 26 and week 104 measurements. The simplified model is considered adequate since the predictive value of profile data from previous visits several weeks earlier is regarded as minimal due to day-to-day variability.

Box plots have been left out and mean curves by time of treatment discontinuation have been clarified only to be done for change from baseline in HbA1c.

The Mixed Procedure

Least Squares Means Estimate

Effect	Label	Margins	Estimate	Standard Error	DF
treatment(avisitn)	V130 IDegLira - IGlar	WORK.BW_MMRM	-3.7498	0.8676	695.7

Least Squares Means Estimate

Effect	Label	t Value	Pr > |t|	Alpha	Lower	Upper
treatment(avisitn)	V130 IDegLira - IGlar	-4.32	<.0001	0.05	-5.4533	-2.0463

16: Fasting plasma glucose after 26 and 104 weeks – change from baseline – supportive statistical analysis – full analysis set

topic_cd=FPG_PLASMA

The Mixed Procedure

Model Information

Data Set	WORK.FPG_MMRM
Dependent Variable	AVAL
Covariance Structure	Unstructured
Subject Effect	USUBJID
Estimation Method	REML
Residual Variance Method	None
Fixed Effects SE Method	Kenward-Roger
Degrees of Freedom Method	Kenward-Roger

Class Level Information

Class	Levels	Values
treatment	2	IDegLira IGlar
region	5	Africa Asia Europe North America South America
avisitn	6	50 60 70 90 110 130

Fasting plasma glucose after 26 and 104 weeks - change from baseline - supportive statistical analysis - full analysis set

treatment(avisitn)	V130 IDegLira - IGlar	-4.31	<.0001	0.05	-0.8320	-0.3104

Mean of 9-point self-measured plasma glucose profile after 26 and 104 weeks – change from baseline – supportive statistical analysis – full analysis set

topic_cd=9PP_SMPG_MEAN_CONV

The Mixed Procedure

Model Information

Data Set	WORK.M9PP_MMRM
Dependent Variable	CHG
Covariance Structure	Unstructured
Subject Effect	USUBJID
Estimation Method	REML
Residual Variance Method	None
Fixed Effects SE Method	Kenward-Roger
Degrees of Freedom Method	Kenward-Roger

Class Level Information

Class	Levels	Values
treatment	2	IDegLira IGlar
region	5	Africa Asia Europe North America South America
avisitn	2	70 130
