PROTOCOL SIGNATURE

I confirm that I have read this protocol, and I will conduct the study as outlined herein and according to the ethical principles stated in the latest version of the Declaration of Helsinki, the applicable ICH guidelines for good clinical practice, and the applicable laws and regulations of the federal government. I will promptly submit the protocol to the IRB for review and approval. Once the protocol has been approved by the IRB, I understand that any modifications made during the course of the study must first be approved by the IRB prior to implementation except when such modification is made to remove an immediate hazard to the subject.

I will provide copies of the protocol and all pertinent information to all individuals responsible to me who assist in the conduct of this study. I will discuss this material with them to ensure that they are fully informed regarding the study treatment, the conduct of the study, and the obligations of confidentiality.

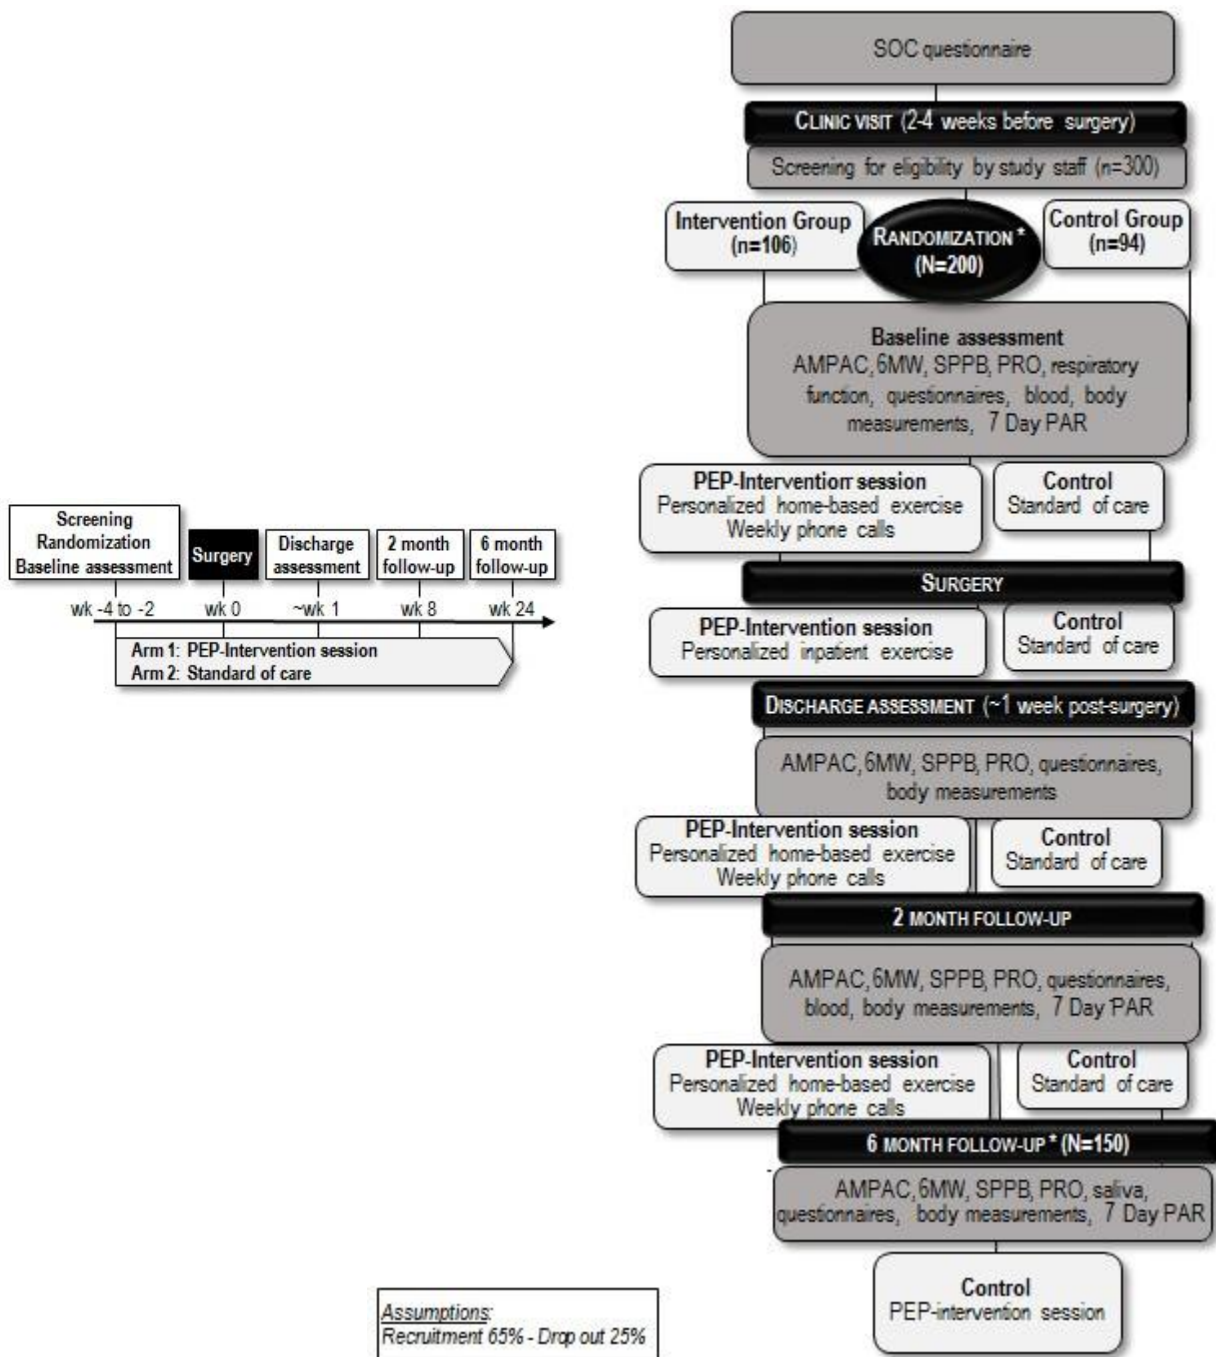

Note: This document is signed electronically through submission and approval by the Principal Investigator in the University of Utah IRB Electronic Research Integrity and Compliance Administration (ERICA) system.

STUDY SUMMARY

Title	A Phase III Randomized Study Comparing the Effects of a Personalized Exercise Program (PEP) Against Standard of Care (No Intervention) in Patients with Stage I-IIIa Non-Small Cell Primary Lung or Secondary Lung Cancer Undergoing Surgical Resection
Short Title	PEP Intervention Study Randomized Clinical Trial
Protocol Number	104671
IND	IND exempt
NCT number	NCT03306992
Phase	3
Design	Randomized two-arm clinical trial comparing a personalized exercise program (Intervention Arm – Group 1) to the standard of care (Control Arm – Group 2: Delayed Intervention Group) in patients with lung cancer (primary stage I-IIIa or secondary)
Study Duration	4 years + duration of COVID-19 adjustments
Study Center(s)	Single center - Huntsman Cancer Institute
Objectives	<p>Primary: Evaluate the improvement in mobility performance via the 6 Minute Walk (6MW) test</p> <p>Secondary:</p> <ol style="list-style-type: none"> 1. Evaluate the improvement in strength, endurance, and balance via the Short Physical Performance Battery (SPPB) test. 2. Gather patient-reported outcomes regarding disease specific symptoms, multidimensional fatigue, common mental health issues, and hypothesized treatment mechanisms, via questionnaires
Number of Subjects	Randomized clinical trial: 200 (approximately 106 men and 94 women), and 300 approached (anticipated recruitment rate 65%)

<p>Diagnosis and Main Eligibility Criteria</p>	<p>Inclusion:</p> <ul style="list-style-type: none"> • Male or female subject aged ≥ 18 years. • Suspected (per the treating physician) diagnosis of primary lung cancer stage I, II, or IIIa OR secondary lung cancer. • Disease amenable to surgical resection to be performed at the Huntsman Cancer Hospital in the opinion of the treating surgeon. • Patients must be able to follow directions and complete questionnaires and exercise diaries in English. • Patients must agree to be randomly assigned to either Intervention or Control Group. <p>Exclusion:</p> <ul style="list-style-type: none"> • Deemed ineligible for surgery by the enrolling physician
	<ul style="list-style-type: none"> • Abnormalities on screening physical exam judged by study physicians or physical therapist to contra-indicate participation in exercise program compliance. • Alcohol or drug abuse as judged by study physicians. • Significant mental or emotional problems that would interfere with study participation, or as assessed by the NCCN Distress Thermometer. Any value higher than 7 on the NCCN Distress Thermometer will trigger further assessment, but ultimately enrollment into the clinical trial will be determined by the enrolling physician.
<p>Study Product, Dose, Route, Regimen and Duration</p>	<p>A personalized exercise regimen based on a patient's AM-PAC score and performed in the outpatient setting starting 2 weeks or more pre-surgery, inpatient for the duration of the hospital stay, and outpatient for approximately 6 months post-surgery.</p>

<p>Statistical Methodology</p>	<p>Primary analysis</p> <p>Power calculations are based on the group effect in an analysis of covariance for the 6MW test at 8 weeks, with baseline 6MW test as covariate. The planned sample size (n = 200) allows for a 25% drop out rate leaving at least 150 subjects evaluable for the primary endpoint. The hypothesis is that the difference in the 6MW distance between the study arms (Intervention vs. Control) will be ≥ 39.95 m. This effect size stems from a meta-analysis where 4 weeks of post-surgery exercise training provided a 39.95 increase in the 6MW distance in NSCLC patients. Consistent with Arbane, SD = 100 m and correlation = 0.5 between repeated 6MW test measurements on the same subject are assumed. Power to detect the treatment effect was estimated by simulation (in R) of an analysis of covariance model with 6MW test at 2 months post-surgery as outcome, treatment group as primary predictor and pretreatment 6MW test as covariate. Pre and post 6MW test was assumed to be bivariate normally distributed.</p> <p>Secondary analyses</p> <p>See section 10 for details.</p>
------------------------------------	--

1 OBJECTIVES

This study is designed to establish whether participation in a personalized exercise program during the pre- and post-operative setting can positively affect physical performance, cardiorespiratory fitness, quality of life, clinical outcomes (hospital length-of stay and readmission rate, complications), and treatment-related costs in patients undergoing surgery for the treatment of stage I-IIIa NSCLC as well as secondary lung cancer when compared to the current standard of care (no exercise program).

1.1 Primary Objective

1.1.1 Evaluate the improvement in mobility performance.

Primary Endpoint: Six Minute Walk (6MW) distance.

1.2 Secondary Objectives

1.2.1 Evaluate the improvement in strength, endurance, and balance.

Secondary Endpoint #1: Short Physical Performance Battery (SPPB) test scores

1.2.2 Gather patient-reported outcomes regarding disease-specific symptoms, multidimensional fatigue, common mental health issues, and hypothesized treatment mechanisms and evaluate differences between arms.

Secondary Endpoint #2: results from PROMIS, FACT-L (Functional Assessment of Cancer Therapy-Lung), FACIT-F (Chronic Illness Fatigue Scale), PSQI (Pittsburgh Sleep Quality Index), BREQ-3 (Behavioral Regulation in Exercise Questionnaire 3), AM-PAC outpatient short form, activity/exercise, tobacco history, mDES, WHI emotions, loneliness, and Subjective Social Status Ladders questionnaires.

Further secondary endpoints to be explored include self-efficacy, social support, disease-related symptoms (e.g., pain, shortness of breath, fatigue), activities of daily life, personal habits, emotions, exercise diaries, demographics, 7-day physical activity recall, background information, diet (measured by the DHQII from the NCI), cancer treatment distress (CTXD) and living conditions.

1.3 Exploratory Objectives

1.3.1 Evaluate changes in biomarker levels, smoking status, microbiome, and body measurements.

Exploratory Endpoint #1: potential prognostic or mechanistic biomarkers, such as inflammatory biomarkers, in serum, plasma, and buffy coat, possible variations in weight and body measurements over the course of the study. Additionally, smoking status post-surgery and microbiome will be assessed.

1.3.2 Evaluate the rate of complications.

Exploratory Endpoint #2: rate of occurrence of pulmonary, cardiac, and other complications requiring treatment (e.g., liver dysfunction, gastric ulcer, wound infection, colitis, depression), readmissions and deaths within the first 30 days after discharge, death and/or hospitalization due to COVID-19 during or after study.

1.3.3 Measure the length of stay post-surgical resection.

Exploratory Endpoint #3: time from surgery to discharge obtained from clinical databases.

1.3.4 Evaluate costs of the PEP intervention on health care utilization and costs from admission to discharge, from discharge to 2 months follow-up, and from 2 to 6 months follow-up.

Exploratory Endpoint #4: total cost of care and utilization for each of the three periods collected through the UUHS VDO, the Utah APCD, the health care utilization questionnaires, the financial strain (COST) questionnaire, and time-line follow-back.

1.3.5 Assess impact of COVID-19 on the study and participants.

Exploratory Endpoint #5: COVID-19 questionnaire.

1.4.2 Analysis of whether the 6 minute walk (6MW) distance may be predicted based on previous 6MW tests completed.

Exploratory Aim #2: Completed 6MW tests.

2 BACKGROUND

2.1 Lung Cancer: A Major Public Health and Clinical Challenge

The incidence and prevalence of lung cancer has risen dramatically. In 1953, primary lung cancer became the most common cause of cancer death in men, while the same occurred for women in 1985 in the United States.¹ Worldwide, lung cancer is one of the most commonly diagnosed cancer types and also the leading cause of death in men.¹ Among the most aggressive cancers, lung cancer causes more deaths than the next three most lethal common cancers combined.¹ The lungs are the most common site for metastatic disease (secondary lung cancers), which are identified in 30-55% of metastatic cancer patients.²

Non-small cell lung cancer (NSCLC) accounts for the majority of primary lung cancer (~85%). Stage I disease (small lesion, no spread in lymph nodes) and stage II disease (larger lesion, no spread in lymph nodes, and involvement of structures such as the chest wall or diaphragm, or involvement of hilar lymph nodes) make up about a third of patients with

NSCLC.¹ Treatment options for lung cancer depend on histology, stage, and patient-specific factors. Randomized clinical trials have established surgical resection of a single lobe of the lung, or lobectomy, as the treatment of choice for operable lung cancer patients in stage I and II,¹ improving survival to up to 75%.^{1,2} For those patients with stage IIIa disease (involvement of ipsilateral mediastinal lymph nodes), surgical resection plays a role after chemoradiation therapy, provided no further spread of disease has occurred, and patients remain medically operable. The lung is also a common site for metastatic spread from other primary cancers (most common: breast, colon, sarcoma, and melanoma). Experience with surgical resection of secondary lung cancers (pulmonary metastasectomy), once the primary cancer has been controlled, has confirmed that resection can substantially prolong survival and potentially cure some patients.³⁻⁸ In 2015, lung cancer accounted for \$13.4 billion in costs out of a total expense of cancer care of \$147.5 billion.⁹ Lung cancer patients often experience multidimensional impairments affecting quality-of-life (QoL) during their course of disease.¹⁰ Impairments result from both symptoms of the disease and comorbidities, as well as side effects of treatment. Interventions aimed at minimizing morbidity would have a significant impact on public and population health.

2.2 Functional Outcomes after Surgery

Surgical resection is the treatment of choice for primary lung cancer patients with stage I to IIIa lung cancer, as it offers the best chance for cure. The goal of surgical resection for lung cancer patients is excision of one or more lobes of the lung that are affected by cancer. For secondary lung cancers, this goal is complete removal of the lesion with adequate margins. Lung cancer patients suffer substantial functional decline and reduced activity levels following surgical lung resection.¹¹⁻¹³ There is a significant deterioration in six minute walk (6MW) distance at five days post-operatively compared with pre-operatively (average of 337m vs. 467m).¹¹ Lung resection is associated with an immediate 12% reduction in exercise tolerance and 18% reduction in pulmonary function.¹² Lung resection also has an impact on post-surgery health-related QoL¹⁴⁻¹⁶ and causes persistent pain following surgical treatment for up to 33% of patients.¹⁷ The postsurgical period is associated with a 20-40% reduction in physiological and functional capacity, particularly in the elderly with comorbidities, who may never return to pre-surgery levels of function.¹⁸⁻²⁰ Additionally, poor pre-surgery physical performance has been shown to increase the risk of mortality,²¹ post-surgery complications, and prolonged functional recovery.²² Thus, the pre-operative and post-operative periods are ideal periods to intervene. Enhancing functional capacity 2-4 weeks prior to a lung resection is feasible and motivates the patient to continue with physical activities and exercises postoperatively, which is essential for optimizing outcomes

2.3 Exercise Training in Oncological Patients

Exercise intervention studies prior to, during, and after cancer treatment consistently show beneficial effects for various physical and psychosocial outcomes.²³⁻³³ The American College of Sports Medicine Roundtable on Exercise Guidelines for Cancer Survivors concluded that exercise training is safe during and after cancer treatments and results in improved physical function, QoL, and cancer-related fatigue in multiple cancer survivor

groups.²⁴ It has been shown that exercise interventions can ameliorate or reverse cancer treatment-induced impairment of physical function and QoL, such as cancer-related fatigue and pain.²⁴⁻³⁷

Several non-randomized intervention studies and ten randomized controlled trials have demonstrated positive effects of pre- or post-surgical exercise intervention in lung cancer patients.^{11,38-59} In a review, Crandall et al. concluded that compared to usual care, exercise interventions among lung cancer patients both pre- and post-surgery are associated with improved cardiopulmonary exercise capacity and muscle strength, and reduced fatigue, post-operative complications and hospital length of stay.⁶⁰ Despite this consistent and convincing evidence, implementation of exercise programs in clinical practice for patients with lung cancer is still low, perhaps due to unacceptable financial and resource demands on the patient and the health care system (e.g., center-based exercise). There are further gaps in the evidence base: Although the majority of exercise studies have demonstrated positive impact, only a small Turkish trial has covered the continuum from pre-surgery to the survivorship period,⁴⁹ and none have used a highly standardized, yet patient-tailored approach. Most of the exercise studies in lung cancer patients have been developed outside of the United States, and there are currently only two American trials recruiting patients, both of which differ substantially in their design. One trial tests a 16-week exercise intervention that starts at least one year following the completion of therapy and requires participants to attend three supervised sessions per week (NCT 01068210). The other trial provides mindfulness-based pulmonary rehabilitation prior to surgery for both lung cancer and COPD patients (NCT 01682850). There is clearly a need for testing innovative exercise interventions in lung cancer patients that can be translated into clinical practice across the entire continuum of care.

2.4 Physical Functioning (AM-PAC Scores) Among Lung Cancer Patients at HCI

The AM-PAC mobility score⁶¹ was implemented as the inpatient mobility assessment tool in June of 2014 within the University of Utah Health Care system (UUHS) and has become a standard mobility measure collected by physical therapists in the University's acute hospitals (see Appendices 1-3). The PEP Study team plans to extend assessments to presurgery visits for the standardized precision exercise program. As part of a pilot study, $n = 63$ AM-PAC scores were collected at Dr. Varghese's clinic from lung cancer patients during their pre-operative outpatient clinic visit. The average score was 54 ± 13 . Patients were 54% female, with mean age of 61 ± 15 years. Overall 44% of patients were categorized as AM-PAC stage 3, indicating that they had difficulty with community mobility. Eighteen % had stage 2, indicating that they had difficulty with mobility within the home. Patients ranging across mobility stages 2-4 are generally capable of performing exercise that will have the greatest likelihood in resulting in positive outcomes. The level of physical function of patients in the clinic can vary widely, reinforcing the PEP concept of an exercise intervention that is tailored for the mobility stage of each patient. No correlations between the AM-PAC score and age, sex, or cancer stage (all $p > 0.05$; $|r| < 0.30$); some 75 year olds had better function than 50 year old patients. This suggests that the AM-PAC score is well-

suited and sufficient to assess physical function, and should be evaluated for appropriate tailoring of exercise interventions.

2.5 Rationale for Conducting the Study

Studies that have investigated the effect of exercise in lung cancer patients undergoing surgery have been center-based and resource intensive, and consequently have not been implemented in the clinical setting.⁶⁵⁻⁶⁷ Pre-operatively, effective exercise programs lasting 6-12 weeks are not feasible since patients with lung cancer do not want to delay surgery. In fact, one randomized controlled trial (RCT)³⁸ was prematurely discontinued because neither patients nor providers were willing to delay surgery longer than 4 weeks. Post-surgery, home-based exercise strategies capable of improving mobility and fatigue levels of patients following surgery for lung cancer and colorectal cancer⁴⁵ have been prohibitively expensive because they required supervised visits by a nurse.³² In addition, these programs have been “one size fits all,” lacking a personalized approach to optimize adherence and efficacy.⁶⁵⁻⁶⁸

To date, no attempt has been made to test a pragmatic and personalized exercise intervention (i.e., face to face visits at clinical contacts, telephone counseling in the home, and personalized exercise prescriptions) before and following surgery for patients with lung cancer. Unfortunately, the application of personalized principles of exercise in randomized controlled trials with cancer survivors (specifically non-breast cancer survivors) is incomplete and inconsistent.⁶⁹ To establish consistency in the exercise prescription while accommodating the exercise to match the patient’s level of mobility, a validated basic mobility assessment tool to create modes and dosages of exercise that can be implemented across the continuum of the pre- and post-operative surgical experience in lung cancer patients may prove to be beneficial. The Activity Measure-Post Acute Care™ (AM-PAC) (described in Figure 2) will be used as the basic mobility assessment tool that prompts the prescribed exercise mode and dose for the patient. The AM-PAC has been developed as a pragmatic measurement system that can be used across care settings and a very broad range of impairments, limitations and diagnoses.⁷⁰ The PEP Study’s approach with the use of AMPAC will address a gap in the care of lung cancer patients, i.e., the underutilization of exercise because it is clinically not pragmatic and it is not known how and when to implement exercise.⁷¹

2.6 Rationale for the PEP Intervention Design

Dr. Ulrich’s previous work with the empirically validated MotivAction intervention will serve as the foundation for the PEP intervention, which will be adapted for lung cancer patients. The Health Action Process Approach (HAPA) describes a general framework for self-regulation and behavior change among individuals with chronic illness.⁷²⁻⁷⁸ The overarching conceptual basis is the social cognitive model⁷⁴⁻⁷⁶ which posits that high levels of both motivation and self-efficacy are necessary for behavior change.²⁹ Thus, in the HAPA model, a key element for lasting behavior change is a motivational shift that instigates a decision and commitment to change. In the absence of such a shift, skill training is viewed as premature.^{74,79,80} As such, the PEP intervention focuses on both enhancing the motivation

to achieve and maintain change, as well as developing the self-efficacy and skills necessary to do so. Many interventions focus largely on either motivation or problem-solving/skills training despite the strong theoretical and empirical bases for doing both. When motivation is addressed, the focus is typically on initiating a change attempt, with little attention given to the motivation to maintain change. Specific components of the PEP intervention include: individualized tailoring of the exercise prescription; individualized tailoring of the counseling based on motivation and self-efficacy to engage in exercise including the use of simple motivational interviewing (MI) ⁷⁹ techniques (e.g., reflective listening, avoiding argumentation; developing discrepancy); identifying barriers to exercising and problem-solving solutions; use of goal setting and self-monitoring (including via the activity tracker); and, implementing specific strategies for improving self-efficacy (e.g., building a series of small achievable goals; practicing specific exercises during the face to face visits to increase mastery (see Figure 1).

In sum, the PEP intervention is a directive but patient-centered approach designed to enhance motivation for change, and increase self-efficacy in a non-confrontational manner. Several meta-analyses and systematic reviews have supported the efficacy of both social cognitive and MI-based interventions for behavior change in general and with respect to cancer patients specifically.⁸¹⁻⁸⁵

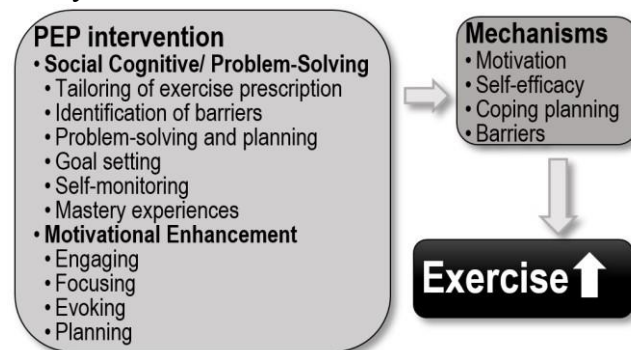

Figure 1: PEP interventions strategies and mechanisms

2.7 PEP Study Pilot

In order to test the feasibility of patient recruitment and study implementation, a pilot study was conducted (IRB 91478, The PEP Study: Precision Exercise Prescription among lung cancer patients, approved 7/3/2016).

Between 7/7/2016 and 10/11/2016, n=18 lung cancer patients were recruited into the intervention program at their pre-surgery consult with Dr. Varghese. Every eligible patient was approached, and all patients approached (100%) agreed to participate in the intervention. Their physical function was assessed with 6MW test, SPPB, and AM-PAC score. The testing and precise exercise prescription was implemented within normal clinic workflow and clinic space by a trained physical therapist (Dr. Barnes) using existing space in the clinic of Thoracic Surgery. The intervention included individually-prescribed exercise modes (mobility, flexibility, callisthenic, aerobic, and resistance) and dosages (low, moderate, high) tailored to the patient's AM-PAC mobility stage.

The baseline observed 6MW distance varied from 209-679m with a mean distance of 467 ± 119 m. Normal 6MW distance for healthy 60-69 year olds is 572m for men and 538m for women. For ten patients, post-operative 6MW distances were obtained prior to 10/15 (max. follow-up time 20 post-operative days within the pilot). Compared to comparable control patients (for whom 6MW distances at comparable pre- and post-time points were available) PEP patients maintained their physical function and experienced a lesser reduction in 6MW distance (median 6.8% decline in PEP and 18.7% in controls, see Figure 1). Although this comparison is not based on a randomized study, it is notable that the decrease (47m) in 6MW distance in the controls exceeded the minimal clinically important distance, despite the time points achieved at this point being very early in the intervention process. To date, only one patient has dropped out (5.5% drop-out rate).

A follow-up phone evaluation of the PEP intervention showed that patients planned to exercise an average of 4.7 days per week and 93% agreed (86% strongly) that exercise should be part of their cancer treatment; 86% also strongly agreed with the statement that they believe that the exercise program will have a positive effect on their cancer treatment. Several patients noted that they loved being in the program and the effort of our team. They emphasized that the exercise intervention helped them immensely with recovery from surgery.

In conclusion, these preliminary results demonstrate that: (1) our team has successfully worked together on the PEP study intervention, generated pilot data, and two scientific abstracts;^{90,91} (2) lung cancer patients differ dramatically in their functional status, independent of age, sex, and stage, requiring individualized interventions; (3) the PEP intervention was feasible within the existing workflow of a high-volume surgical clinic, with only the addition of a physical therapist to manage the intervention; (4) the PEP intervention is welcomed by patients and appears to show early efficacy; and (5) our assumptions for anticipated patient recruitment (65%) and drop-out rates (15%) are conservative. Overall, this pilot work sets the base for a successful clinical trial.

3 STUDY DESIGN

3.1 Description

This is a Phase 3 study aimed at investigating the effects of a personalized exercise program (PEP) in NSCLC patients (stage I, II, IIIa) and secondary lung cancer patients undergoing surgical treatment at the University of Utah and comparing the intervention to the current standard of care (no exercise program).

Eligible patients will be randomized between two arms (1:1 ratio) prior to the surgery and will be followed for approximately 6 months post-surgery:

- An Intervention Arm (referred to in materials as Group 1), which features pre- and post-surgery PEP interventions.
- A Control Arm (referred to in materials as Group 2), which does not include a personalized exercise program (the standard of care). Patients randomized to Group

2 will be given the opportunity to participate in a PEP-intervention session providing exercise counseling after the 6 month assessment and will receive a free activity tracker for their participation.

3.2 Number of Patients

The target enrollment for the randomized clinical trial is 200 patients (approximately 106 men and 94 women). It is estimated that 300 patients will be approached about the study, which will achieve a conservative recruitment rate of 65%.

3.3 Number of Study Centers

This study will open at a single center at the Huntsman Cancer Institute. Study procedures may be performed at the Huntsman Cancer Hospital, the University of Utah Farmington clinic, or remotely. The remote option will only be used in circumstances when staff is not able to perform study procedures on site. Staff will take necessary steps to ensure participant safety and confidentiality at all times when performing procedures remotely.

3.4 Duration

Participants will be recruited over the course of 33 plus duration of COVID-19 adjustments months. The estimated total duration of the study from the first enrollment to the end of the last 6-months follow-up is 4 years plus duration of COVID-19 adjustments.

4 ELIGIBILITY CRITERIA

This eligibility checklist is used to determine patient eligibility and filed with investigator's signature in the patient research chart.

Patient No. _____ **Patient's Initials: (L, F, M)** _____

4.1 Inclusion Criteria

Yes/No (Response of "no" = patient ineligible)

- 4.1.1 _____ Male or female subject aged ≥ 18 years.
- 4.1.2 _____ Suspected (per the treating physician) diagnosis of primary lung cancer stage I, II, or IIIa OR secondary lung cancer.
- 4.1.3 _____ Disease amenable to surgical resection in the opinion of the treating surgeon.
- 4.1.4 _____ Patients must be able to follow directions and complete questionnaires and exercise diaries in English.
- 4.1.5 _____ Patients must agree to be randomly assigned to either Intervention or Control Group.

4.2 Exclusion Criteria

Yes/No (Response of "yes" = patient ineligible)

- 4.2.1 _____ Deemed ineligible for surgery by the enrolling physician
- 4.2.2 _____ Abnormalities on screening physical exam judged by study physicians or supervising physical therapist to contraindicate participation in exercise program compliance.
- 4.2.3 _____ Alcohol or drug abuse as judged by study physicians.
- 4.2.4 _____ Significant mental or emotional problems that would interfere with study participation, or as assessed by the NCCN Distress Thermometer. Any value higher than 7 on the NCCN Distress Thermometer will trigger further assessment, but ultimately enrollment into the clinical trial will be determined by the enrolling physician.

I certify that this patient meets all inclusion and exclusion criteria for enrollment onto this study.

Time

5 INTERVENTION

5.1 Group 2 Delayed Intervention Group

Patients randomized to Group 2 will not experience any changes in the standard of care for lung cancer patients according to their cancer stage. Although patients are encouraged to increase walking both in the pre-surgery and post-surgery period, there is no formalized pre-surgery exercise program. Upon study completion (at the 6 month post-surgery follow-up visit), participants in Group 2 will be offered a PEP-intervention session with precision exercise counseling and receive a free activity tracker.

5.2 Group 1-Intervention Group

The PEP intervention involves a combination of home-based exercise as well as in-patient exercise. The exercise modes will include basic transfer and calisthenics mobility, aerobic, and resistance exercises and will be performed in various postures (supine, sitting, standing, and walking) with variable challenges (level walking, bending, inclines, steps, and squatting).

For patients randomized to Group 1, the PEP intervention will be personalized, implemented, and modified (based on the patients AM-PAC mobility stage) by a licensed physical therapist in face-to-face, virtual, or phone meetings (~30-40 minutes). An exercise education manual, specifically developed for this study, will be used by the physical therapist to educate the patients on all aspects of starting and maintaining the exercise intervention.

5.2.1 Inpatient Sessions

The post-surgery inpatient PEP intervention will be performed under the supervision of the physical therapist in accordance with the exercise education manual and the patient's AM-PAC mobility stage.

5.2.2 Home-Based Exercise

The outpatient exercises will be performed both pre- and post-surgery and will be done at home, the HCI Wellness Center, a recreational center, or similar locations.

The study physical therapist will go over (verbally and in writing) the individual exercise modes and dosages to be performed at home. The individual modes and dosages to be performed at home can also be discussed via phone and the physical therapist may email or send through MyChart the exercise instruction sheets. Although individually-prescribed, the exercise mode and dosage will be standardized with respect to the patient's AM-PAC mobility stage (as shown in Figure 2). For example, a patient in AM-PAC mobility stage 3 will progress from walking on level surfaces for 10 minutes per day at a "somewhat hard" perceived exertion with the ability to talk but not sing during walking. The rate of steps/minute will be ~100. Additionally, this patient will also perform squatting exercise at the same perceived exertion for short bouts that add up to 5 minutes

per day. These aerobic and resistance exercises will be progressed to 20 minutes and 10 minutes per day respectively as they progress to AM-PAC mobility stage 4.

Patients will be given access to instruction sheets demonstrating exercise modes along with exercise tools (e.g., light weights and external resistance bands), tracking diary/calendar, and activity tracker (see note below) for the home-based exercise program. These instruction sheets may be emailed, mailed, or sent through the participant's electronic medical record (MyChart).

Telephone calls or TeleHealth interactions between the participant and the study team will take place weekly to answer questions, optimize patient engagement, and adjust exercise prescriptions remotely as needed. These interactions will be based upon the Motivation and Problem Solving (MAPS) approach, which draws on key aspects of motivational interviewing (MI), cognitive-behavioral therapy, chronic care models, and case management/patient navigation. These weekly phone calls may either be delayed or unsuccessful dependent on the participant's schedule, availability, and whether or not they answer. However, study staff will make an effort to reach the participant if the participant continues to not answer or return the phone calls. In instances where a participant has felt burdened by these phone calls, research staff may perform the calls less frequently for these participants to maintain patient retention. Study staff may utilize text messaging and/or email in order to remind participants of future appointments/calls or to coordinate a day and time to reach the participant by phone. If study staff cannot get ahold of the participant, this will not be considered a deviation. Study staff may also text and/or email the participants to send reminders, schedule study procedures, etc.

Ongoing monitoring of attitudes and barriers to exercise will occur and strategies for encouraging uptake of the exercise intervention will be individually tailored. U of Utah TeleHealth capabilities, including video chat, will be used to augment telephone communications.

Note: the activity tracker, a consumer wearable device (e.g., Fitbit Zip Wireless Activity Tracker), will be used as a pragmatic motivational and self-monitoring tool to improve participant exercise efficacy and home exercise program adherence.⁸⁶

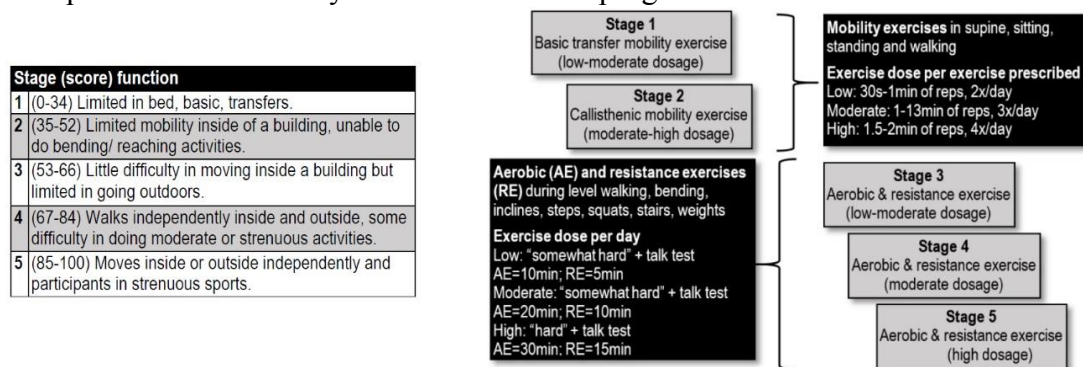

Figure 2: AM-PAC stages (according to Arbane) and corresponding exercise modes and dosages.

5.2.3 Interruption and Discontinuation

The PEP intervention is already personalized, implemented, and modified based on an individual's patient characteristics. However, if, at any time during the study a participant develops an illness that contraindicates exercise in the opinion of the enrolling physician (including but not limited to those described in exclusion criterion 4.2.1), the patient's primary care physician will be consulted regarding whether and when it would be safe to re-start the exercise program.

Should any participant develop any condition that would limit their ability to fully participate in the prescribed protocol, the participant would be temporarily, or if necessary permanently, withdrawn from the study.

† **Only due for patients participating in the PEP intervention**

1. Body measurements will include height, weight, waist and hips measurements. Participants may receive these results if they are interested.
2. PROMIS is a clinic-based evaluation. Study staff will be obtaining this more frequently than required by clinic for the purposes of the study.
3. Materials include an exercise packet (with exercise tool), diary/calendar, and activity tracker at baseline and new tracking diary/calendars at the follow-up visits.
Participants may receive their exercise diary results if they are interested.
4. There will be no activity review at baseline (no activity started) and during the inpatient stay or at discharge (since the PEP intervention is on hold).
5. While inpatient the physical therapist will assess the patient (including AM-PAC scoring) as needed depending on the patient's condition.
6. Activity review + AM-PAC scoring *could* lead to an adjustment in exercise mode / dosage as well as the patient being given a new version of the tracking diary.
7. See details in Section 7.

7 QUESTIONNAIRES

7.1 Standard Questionnaires

The listed questionnaires below with their included questionnaire instruments may be given to all participants in the study. However, in instances when it isn't feasible to give a participant one of these standard questionnaires, a short form questionnaire (listed in 7.2.) will be provided in clinic or given to the participant to take home. The short form questionnaires may also be given to participants who have stated the questionnaires are time consuming or for participants who have not completed previous study questionnaires. Questionnaires may be sent via email, mail, or the participant's electronic medical record (MyChart).

8 STUDY PROCEDURES

8.1 Pre-Surgery Clinic Visit

During their pre-surgery clinic visit (which typically takes place 2-4 weeks prior to surgery as long as surgery is not delayed), all potential lung cancer patients who are surgical candidates (as determined and approved by the surgeon) will be approached about the PEP study. Enrollment may be postponed, and the decision to do so is dependent on all three principal investigators' discretion. This visit may be completed 1 week or up to 6 months prior to surgery depending on the health of the patient and surgical policies. This window may increase if patient and surgical policies require it. Patients who are interested and potentially eligible will undergo the following procedures either in the clinic space or at the Population Sciences (HOPE) clinic located in HCI Research North. All procedures listed below can, as is practical and applicable, also be performed by the study team and participants via telephone, text, email, snail mail, and/or MyChart:

- Informed consent. Consenting may be performed remotely, via phone, video chat, mail and/or email in situations where study staff is unable to consent in person. A copy of the signed consent form may be mailed or emailed to the participant. The process for consenting when unable to do so in person will include the following:
 - A brief introduction of the study from the treating surgeon.
 - Study staff will be notified of the potential participant from the treating surgeon or their clinic staff.
 - The research staff will attempt to contact the potential participant by phone to introduce the study. An email, text message, or message through MyChart may be sent if the patient does not answer.
 - Once the potential participant is reached by phone, the research team will discuss the study and email, mail, or send the consent form via MyChart if the patient is interested.
 - The patient will be given directions to sign the consent form (either personally or electronically) and email the signed copy back to study staff. Study staff will sign then sign the consent form upon receipt.
 - A copy of the signed consent form will be emailed, mailed, or sent through MyChart to the participant.
 - Study staff will coordinate a day and time to meet with the participant to perform study procedures that are required in person. Any procedures that may be completed remotely can be completed before the scheduled date and time.
- Verification of the patient's eligibility for the study. The enrolling physician may sign the eligibility criteria via email, if necessary, however staff will try to receive their signature in person.
- Randomization. This may be completed remotely.
- Baseline assessments by study staff including:
 - Body measurements (height, weight, waist and hips measurements). Staff will attempt to complete the body measurements in clinic, however the participant

may perform the measurements themselves at home. A measuring tape with the form to document the measurements may be mailed, emailed, via MyChart or provided to the participant directly. The participant may then perform the measurements themselves then return the form to staff via a prepaid envelope, email or via MyChart.

- Medical history, medication use. (reviewed and assessed by clinic staff)
- AM-PAC mobility score (via the AM-PAC outpatient form). Staff may perform the AM-PAC with the participant via phone (remotely), if the form cannot be given in clinic.
- 6 Minute Walk Test (6MW) and Short Physical Performance Battery (SPPB). Efforts will be made to ensure consistent 6MW and SPPB testing conditions throughout data collection for each participant, but some modifications may be necessary during the COVID19 pandemic. These results may be mailed, emailed, sent via MyChart or recorded verbally via the video platform.
- Baseline questionnaires and PROMIS (all patients – details in Section 7). The PROMIS may be completed up to 1 week before and 3 weeks after the presurgery clinic visit. Staff will attempt to have PROMIS completed in clinic, but may mail, email, send through MyChart or perform it via phone either on site or remotely. The follow-up questionnaires may be mailed before or after the visit or given to participant at the visit. Participants then may take the questionnaires home to be completed and returned the following weeks after the visit. Participants may also complete the questionnaire via phone with study staff (either on site or remotely) after being seen in clinic if they wish. The questionnaires may also be sent via email, mail, or the participant's electronic medical record (MyChart). Staff will remind participants at least once to complete and return the questionnaire. It will not be considered a deviation if the questionnaire is not received as long as an attempt to remind the participant has been made.
- Standard-of-Care (SOC) questionnaire (completed by all clinic patients regardless of participation in study). This questionnaire and the baseline questionnaire may be completed on the day of the pre-surgery clinic visit up to the day of surgery. Staff will remind participants at least once to complete and return the questionnaire. It will not be considered a deviation if the questionnaire is not received as long as an attempt to remind the participant has been made.
- 7-Day Physical Activity Recall (completed via phone or remotely for baseline). This may be completed up to 2 weeks before visit. It will not be considered a deviation if the 7-Day Physical Activity Recall is not received as long as three attempts are made.

Patients randomized to Group 1 will also receive the following:

- Exercise packet (with exercise tool), instruction for access to supplementary instructional video (if needed), tracking diary/calendar, the group 1 welcome letter, the 'Making Exercise Happen' factsheet, 'PEP Team Introduction' and activity tracker for

the home-based pre-surgical exercise program. The tracking diary/calendar results may be given to participants who request it. The tracking diary/calendar and exercise packet may be sent via email, mail, or the participant's electronic medical record (MyChart). It will not be a deviation if a participant does not return their diary as long as staff attempts to remind the participant to return it or if the participant declines to do it. The activity tracker may be mailed to the participant if staff is unable to provide it in clinic.

- Individual instruction by physical therapist (verbal and written) about the individual exercise modes and dosages to be performed at home and first PEP intervention. This may be administered in person, via phone, email, video chat, or remotely.

Patients randomized to Group 2 will receive the Group 2 welcome letter, 'Making Exercise Happen' factsheet, and the 'PEP Team Introduction' forms in person, mail, email, or MyChart.

Staff may forego any of the above procedures if clinic policy does not allow it (e.g. illness, virus outbreak, etc.).

If patients request to receive study materials and measurement results, the following may be given, mailed, emailed, or sent via MyChart:

Copy of exercise diary, 6MW, and their body measurements.

8.2 In the Weeks Leading to Surgery (Outpatient)

During the time before the surgery, patients randomized to Group 1 will complete a daily PEP intervention as instructed by the physical therapist and record their activity on the tracking diary/calendar. The window before surgery may increase or decrease dependent on whether the patient is clinically and physically ready for surgery, as well as current surgical policies.

Weekly telephone calls or TeleHealth interactions (including video chat) between the patient and the study team will take place to answer questions, review exercise tracking/diary, and optimize patient engagement. Ongoing monitoring of attitudes and barriers to exercise will occur and strategies for encouraging uptake of the exercise intervention will be individually tailored. If needed, adjustments to the mode/dose of the exercise regimen will be made at the discretion of the physical therapist. These weekly phone calls may either be delayed or unsuccessful dependent on the participant's schedule, availability and whether or not they answer. However, study staff will make an effort to reach the participant if the participant continues to not answer or return the phone calls. In instances where a participant has felt burdened by these phone calls, research staff may perform the calls less frequently for these participants to maintain patient retention. Study staff may utilize text messaging and/or email in order to remind participants of future appointments/calls or to coordinate a day and time to reach the participant by phone. Study staff may also text and/or email the participants to send reminders, scheduling study procedures, etc..

8.3 Pre-Anesthesia Visit

- Correlative blood samples collection. Additional blood samples may be drawn before, during, or after this visit if needed. A blood questionnaire may be completed during the process of the blood draw, either before or after, to assist the study team with evaluation of the sample quality. Study staff may call the participant to ask questions from the blood questionnaire. If a participant declines the blood draw, the blood questionnaire will not be completed. Blood will not be collected if the Biospecimen and Molecular Pathology Shared Resource at the Huntsman Cancer Institute is closed at the time of collection.

8.4 Inpatient Stay

The inpatient stay post-surgery is expected to last from 5 to 10 days and may include assessments by the study physical therapist or inpatient physical therapists for all patients. The frequency of the assessments will follow standard of care guidelines and is dependent on the patient's condition.

8.5 Hospital Discharge Visit

This visit is directly aligned with the patient's clinic visits and is contingent on clinic and patient availability. The visit may occur 1 to 8 weeks from the date the patient was discharged from the hospital (discharge date) depending on the health of the patient and surgical policies. This window may increase if patient and surgical policies require it. The following procedures will be completed at the discharge visit. All procedures listed below can, as is practical and applicable, also be performed by the study team and participants via telephone, text, email, snail mail, and/or MyChart:

- Assessment by physical therapist including:
 - AM-PAC mobility score (outpatient form). Staff may perform the AM-PAC with the participant remotely if the form cannot be given in clinic.
 - Education on acute and sub-acute post-operative mobility limitations.
 - 6 Minute Walk test (6MWT) and Short Physical Performance Battery (SPPB). Efforts will be made to ensure consistent 6MW and SPPB testing conditions throughout data collection for each participant, but some modifications may be necessary during the COVID19 pandemic. Attempts will be made to complete both the 6MW and SPPB, but will not be completed situations where it is not safe for the participant per the treating physician or study physical therapist's discretion. Participants may have their results if they request them. Staff will attempt to complete the body measurements in clinic; however, the participant may also perform the measurements themselves at home. A measuring tape with the form to document the measurements may be mailed, emailed or provided to the participant directly. The participant may then perform the measurements themselves then return the form to staff via a prepaid envelope, email or via MyChart.
- Follow-up questionnaires and PROMIS (see section 7 for details). Staff will attempt to have PROMIS completed in clinic, but may mail or administer it via phone. The follow-up questionnaires may be mailed before the visit or given to participant at the

visit. Participants then may take the questionnaires home to be completed and returned the following weeks after the visit. Participants may also complete the questionnaire via phone with study staff after being seen in clinic if they wish. It is also an option for staff to email or send the questionnaire through the participant's electronic medical record (MyChart). The questionnaires and PROMIS may be administered remotely. The discharge questionnaire may be completed on the date of the visit up to the 2 month visit. It will not be considered a deviation if the questionnaire is not received as long as three attempts to remind the participant have been made.

- Distribution of tracking diary/calendar (2 month follow up only). The tracking diary/calendar results may be given to participants who request it. The diary may also be sent via email, mail, or the participant's electronic medical record (MyChart), if needed. It will not be a deviation if a participant does not return their diary as long as staff attempts to remind the participant to return it or if the participant declines to do it. The activity tracker may be mailed to the participant if staff is unable to administer in clinic.

Patients randomized to Group 1 will also receive the following:

- Review of home exercises and, if needed, adjustments to the mode/dose of the exercise regimen. This may be done in person, via phone, email, or remotely. The exercises may be mailed or sent via email or MyChart.

Staff may forego any of the above procedures if clinic policy does not allow (e.g. illness, virus outbreak, etc.).

If patients request to receive study materials and measurement results, the following may be given, mailed, emailed, or sent via MyChart:

Copy of exercise diary, 6MW, and their body measurements.

8.6 During the Follow-Up (Outpatient)

For patients randomized to Group 1, weekly telephone calls or TeleHealth interactions between the participant and the study team will continue as described in section 8.2.

8.7 Follow-Up Clinic Visits (2 and 6 Months Post-Surgery).

These visits are directly aligned with the patient's clinic visits and is contingent on clinic and patient availability. During times of unforeseen external impact, the 2 month visit may occur up to 4 months post-discharge and the 6 month visit may be completed up to one year post-discharge depending on the health of the patient and surgical policies. This window may increase if patient and surgical policies require it. The 6 month questionnaire may be completed on the date of the visit up to one year after the visit. The following procedures will be completed at the follow-up visits scheduled approximately 2 and 6 months after surgery:

- Assessment by physical therapist including AM-PAC mobility score (outpatient form). Staff may administer the AM-PAC with the participant remotely if the form cannot be given in clinic.
- 6 Minute Walk test (6MW) and Short Physical Performance Battery (SPPB). Efforts will be made to ensure consistent 6MW and SPPB testing conditions throughout data collection for each participant, but some modifications may be necessary during the COVID19 pandemic. Attempts will be made to complete both the 6MW and SPPB, but will not be completed situations where it is not safe for the participant per the treating physician or study physical therapist's discretion. These results may be mailed, emailed, sent via MyChart or recorded verbally via the video platform. Follow-up questionnaires and PROMIS. The PROMIS may be completed up to 3 weeks before or 3 weeks after each follow-up clinic visit. The follow-up questionnaires may be mailed before the visit or given to participant at the visit. Participants then may take the questionnaires home to be completed and returned the following weeks after the visit. Participants may also complete the questionnaire via phone with study staff after being seen in clinic if they wish. It is also an option for staff to email or send the questionnaire through the participant's electronic medical record (MyChart). The PROMIS and questionnaires may be administered remotely, if needed. It will not be considered a deviation if the follow-up questionnaires are not received as long as at least three attempts to remind the participant have been made.
- 7 Day Physical Activity Recall (performed via phone, remotely or on-site, or during the visit). This may be completed up to 2 weeks before the visit. It will not be considered a deviation if the 7-Day Physical Activity Recall is not received as long as three attempts are made.
- Body measurements (baseline, discharge, 2 month and 6 month follow up). Staff will attempt to complete the body measurements in clinic under appropriate safety precautions, however the participant may perform the measurements themselves at home. A measuring tape with the form to document the measurements may be mailed, emailed or provided to the participant directly. The participant may then perform the measurements themselves then return the form to staff via a prepaid envelope, email or via MyChart.
- Optional correlative blood samples collection (2 months follow-up only). Additional blood samples may be drawn at this time point, if needed. The blood sample may be collected up to 3 weeks before or after the visit if the patient is having their blood drawn as standard of care in order to prevent additional blood draws. A blood questionnaire will be completed during the process of the blood draw, either before or after, to assist the study team with evaluation of the sample quality. Study staff may call the participant remotely to perform the blood questionnaire. If a participant declines the blood draw, the blood questionnaire will not be completed.
- Optional saliva samples (6 months follow-up only). A saliva questionnaire will be completed during the process of collecting the saliva, either before or after, to assist the study team with evaluation of the sample quality. Study staff may call the participant remotely to administer the saliva questionnaire. The blood and saliva will

not be collected if the Biospecimen and Molecular Pathology Shared Resource at the Huntsman Cancer Institute is closed at the time of collection. Saliva samples will not be completed during the COVID-19 outbreak to ensure study personnel safety. The collection of saliva samples may resume if the study team decides the risk to study personnel safety is minimized.

Patients randomized to Group 1 will also receive in person, mail, via email, text, or MyChart the following:

- Review of tracking diary/calendar. It will not be a deviation if a participant does not return their diary as long as staff attempts to remind the participant to return it or if the participant declines to do it..
- If needed, adjustments to the mode/dose of the exercise regimen.
- A thank you letter only at the 6 month visit.

Patients randomized to group 2 will receive in person, mail, via email, text, or MyChart the following at the 6 month visit:

- A thank you letter
- The activity tracker with information relating to the tracker.
- Staff will offer the option to receive personalized exercises, but the participant may decline.

Staff may forego any of the above procedures if clinic policy does not allow (e.g. illness, virus outbreak, etc.).

If patients request to receive study materials and measurement results, the following may be given, mailed, emailed, texted, or sent via MyChart:

Copy of exercise diary, 6MW, or body measurements.

8.8. Compensation

- **Participants will be compensated up to \$60 dollars once they have completed their 6 month visit for completing the study. The compensation will be in the form of a gift card. Study staff may either provide the gift card in clinic or mail the gift card (s) to participants. A form will be included with the mailed gift card for the participant to sign, confirming the participant received the gift cards. Instructions will be provided to the participant to sign and return the form back to staff via a pre-paid envelope.**

9 CRITERIA FOR EVALUATION OF ENDPOINTS

9.1 Physical Function Performance

The primary endpoint associated with the evaluation of improvement in mobility performance is the result of the 6MW test (6MW distance). The distance patients can walk indoors on a 25

to 30 meter level smooth-surfaced track over the course of 6 minutes will be measured at baseline as well as at the time of discharge and at the 2 and 6 months follow-up. Efforts will be made to ensure consistent 6MW testing conditions throughout data collection for each participant. Median distances will be computed for each arm at the various time points and the expected post-surgery decline and recovery during follow-up will be compared between arms. To accommodate policy and concerns surrounding the COVID-19 pandemic, the current 6MW test track of 25 meters may need to change on occasion and relocate from Clinic 1A to areas with walking tracks that range between 25-30 meters. Because all other operating procedures surrounding the 6MW test will remain identical we do not expect any issues related to the fidelity of the test.

A secondary endpoint associated with the evaluation of improvement in physical performance is the result of the short physical performance battery test. The SPPB score (ranging from 1 to 12) will be obtained for each patient at the time points described above. Medians will be obtained and compared for each arm.

9.2 Patient Reported Outcomes

Questionnaires aimed at measuring disease specific symptoms, multidimensional fatigue, common mental health issues (i.e., depression, anxiety, and alcohol use), and hypothesized treatment mechanisms will be obtained on this study at baseline, at discharge, and at the 2 and 6 months follow-up. The effect of the PEP intervention on patient reported outcomes will be evaluated by comparison between each arm of the study.

9.3 Exploratory Objectives

Data gathered from all patients who received the PEP intervention and pertaining to the quality of the intervention, participation in the intervention, and attitudes toward exercise (obtained via questionnaires) will be analyzed.

Additionally, the effects of the PEP intervention on the following will be evaluated by comparison between each arm of the study:

- Rate of complications (pulmonary and cardiac events, other complications requiring treatment [e.g., liver dysfunction, gastric ulcer, wound infection, colitis, depression], readmissions, and deaths within the first 30 days after discharge).
- Length of stay post-surgical intervention.
- Death and/or hospitalization post-study relating to COVID-19.

Finally, the effects of the PEP intervention on the following will be evaluated by comparison between each arm of the study:

- Total cost of care and utilization (obtained through the UUHS VDO, the Utah APCD, the health care utilization questionnaires, the financial strain (COST) questionnaire and time-line follow-back).
- Levels of potential prognostic or mechanistic biomarkers such as inflammatory biomarkers, in serum, plasma, and buffy coat. Additionally, smoking status post-surgery and microbiome will be assessed.

- Assess the impact of the Coronavirus (COVID-19) on the study and its participants during the outbreak. A limited dataset (including first name, email address, zip code and study ID) may be shared with IRB_00140849 'Exemption Umbrella Protocol- HCI projects to facilitate a larger review of the impact of COVID-19 on all patient populations listed in the umbrella protocol.

Additional Exploratory Objectives:

- Comparison of paired 6 minute walk tests completed by the same patients in clinic and remotely. Prediction of in clinic 6 minute walk test from remote 6 minute walk test of the same patient.
- Prediction of missing 6MW from completed 6MW and other covariates.

The following information will be abstracted from each participant's medical record to allow the UUHS VDO and Utah APCD staff to provide information on the total cost of care and utilization. It has been required by the UUHS VDO staff that the protocol outlines the specific medical record information before they will provide their services. However, any additional medical record information not already outlined below may also be used by study staff.

- Demographics:
 - Age at time of first clinic visit
 - Date of birth
 - Gender
 - Body Mass Index
 - weight
 - Patient's Zip Code (to help with calculation of distance to Huntsman)
 - Race: Caucasian, Black, Hispanic, Asian, Native American, Other
 - Zubrod Performance Scale
 - 0 = Normal activity, no symptoms
 - 1 = Symptoms but fully ambulatory
 - 2 = Symptoms but in bed less than 50% of the time
 - 3 = Symptoms but in bed >50% but less than 100%
 - 4 = Bedridden
 - 5 = Moribund
- Risk Factors for complications (Yes/No answers)
 - Weight loss in past 3 months greater than 3 kgs (captured in questionnaire)
 - Infection at the time of initial clinic visit (e.g., pneumonia)
 - Co-morbidities
 - Hypertension
 - Steroid use
 - Congestive Heart Failure

- Coronary Artery Disease
 - Peripheral Vascular Disease
 - Preoperative Chemotherapy
 - Preoperative Radiation therapy
 - Prior Cardiothoracic Surgery
 - History of Stroke
 - Diabetes
 - Renal insufficiency history (documented history of renal failure and/or a history of creatinine value > 2.0)
 - Other co-morbidity not listed above
- Tobacco Use
 - Use of smokeless tobacco
 - Cigarette use
 - Pack Years (no. of packs per day x no. of years smoking)
 - Tobacco Pipe
 - Tobacco Other
- Status of Tobacco Use History
 - Never Smoker
 - Active smoker at time of clinic visit (this patient will be classified for our paper eventually as a recent quitter, as we have a policy of not operating on those who continue to smoke)
 - Quit smoking >12 months before surgery (remote smoker)
- Pulmonary Function Tests
 - Forced Expiratory Volume in 1 second (FEV1): Value and % predicted
 - Diffusion Capacity (DLCO): Value and % predicted
- Outcomes
 - Procedure Type (VATS [either traditional or robot] OR Thoracotomy)
 - Amount of Lung Resection (Wedge Resection, Segmentectomy, Lobectomy, OR Pneumonectomy)
 - Inpatient AMPAC Score at time of discharge
 - Complications postoperatively
 - Pneumonia
 - Air Leak greater than 5 days
 - Adult Respiratory Distress Syndrome (ARDS)
 - Pulmonary Embolus
 - Initial ventilator support >48 hours in the postoperative period
 - Reintubation
 - Tracheostomy
 - Cardiac arrhythmias
 - Bleeding
 - Neurological Event
 - Renal Event
 - Chylothorax

- Wound Infection
 - Other Infection
 - Length of Inpatient Stay
 - Lung Cancer Pathology Description
 - Primary or Secondary
 - If Primary, Lung Cancer Stage
 - Discharge Date
 - Discharge Location (Home, Skilled Nursing Facility, Rehab facility)
 - Readmission within first 30 days after discharge (to Hospital)
 - Additional Therapy after Surgery
 - Postoperative Chemotherapy
 - Postoperative Radiation Therapy
 - Clinic Visits After Discharge
 - Routine (1-2 weeks, 2 months, 6 months)
 - Additional clinic visits to routine
- Financial/Cost
 - type of insurance
 - -service start/end date
 - -weight
 - -inpatient/er visit indicator
 - -outpatient/office visit indicator
 - -physical therapy indicator
 - -home nursing visit
 - -skilled nursing facility/rehabilitation hospital
 - -charge amount
 - -ICD-9/10 diagnosis codes
 - -ICD-9/10 procedure codes
 - -CPT codes

10 STATISTICAL CONSIDERATIONS

10.1 Randomization

Randomization will have a uniform 1:1 allocation ratio with block sizes of 8. The random allocation sequence will be stratified by the mobility staging (high vs. low) provided by the pre-treatment AM-PAC stage and whether it is a primary or secondary lung cancer diagnosis, based on primary data (as described in section 2.4), the AMPAC stage is sufficient to assess physical function.

10.2 Outcomes, Power, and Sample Size Considerations

Objectives and endpoints are described in Section 1. Covariates used in sensitivity or mediation analysis of the objectives will be age, gender, baseline smoking status, primary or secondary lung cancer, neoadjuvant treatment, tumor stage, baseline level of outcome, pain, and sleep.

Power calculations are based on the group effect in an analysis of covariance for the 6MW test at 8 weeks, with baseline 6MW test as covariate. The planned sample size ($n = 200$) allows for a 25% drop out rate (the main reasons for drop outs observed during the pilot study was found to be complications or poor health status preventing follow-up visits as well as distance to study site), leaving at least 150 subjects evaluable for the primary endpoint. The hypothesis is that the difference in the 6MW distance between the study arms (Intervention vs. Control) will be ≥ 39.95 m. This effect size stems from a meta-analysis where 4 weeks of post-surgery exercise training provided a 39.95 increase in the 6MW distance in NSCLC patients.⁸⁷ Consistent with Arbane,¹¹ $SD = 100$ m and correlation = 0.5 between repeated 6MW test measurements on the same subject are assumed. Power to detect the treatment effect was estimated by simulation (in R) of an analysis of covariance model with 6MW test at 2 months postsurgery as outcome, treatment group as primary predictor and pretreatment 6MW test as covariate. Pre and post 6MW test was assumed to be bivariate normally distributed.

10.3 Primary Endpoint Analysis

Analyses will include all patients that are evaluable for our primary endpoint (expected at least $n=150$). The primary outcome will be the group effect for an analysis of covariance model with 6MW test at 2 months post-surgery as outcome and pretreatment 6MW test as covariate, tested at the nominal two-sided 0.05 significance level. A sensitivity analysis will be performed with additional adjustment variables (listed as covariates in Section 10.1). Missing data will be handled using multivariate imputation by chained equations⁸⁸ as implemented in the R package “mice”.

10.4 Other Endpoint Analyses

The approach to testing for group differences for each continuous outcome (e.g., quality of life and fatigue summary scales, length of stay after surgical resection, cost) will be to test for the group effect in an analysis of covariance model with adjustment for covariates listed in Section 10.1 as well as baseline values of the outcome variable when available.

Cost data and utilization data are typically positively skewed with some patients having very high costs/utilization. To reflect the distributions of cost and utilization, a generalized linear regression (GLM) with log link and gamma distribution and the generalized beta of the second kind (GB2) will be applied. To examine health care utilization, a Negative Binomial Regression (NBR) will be used to handle over dispersion of patient visits.

The proportion of patients who continue to smoke post-surgery is expected to be too small to include as a reliable adjustment variable or outcome ($\sim 5\%$).⁸⁹ Former smokers will be tested (saliva) at the 6 month clinic visit to assess smoking recidivism. A separate descriptive analysis will be performed in the subset of smokers.

An analogous approach will be used for endpoints coded as binary variables (complications, readmission) using logistic regression models instead of analysis of

covariance models. If diagnostics plots show significant deviation from model assumptions, then a separate sensitivity analysis will be performed using appropriate robust regression methods such as those available in the “robust base” package in R.

The study design provides 96% power to detect a 10 point increase in FACT-L in the Intervention Group compared to the Control Group, similar to the effect of aerobic training on FACT-L reported in Jones.⁴⁶

Bland-Altman analysis will be used to analyze agreement between remote and in clinic 6MW and for calculation of 95% confidence intervals on limits of agreement. The intra-class correlation coefficient will also be reported. Gaussian linear regression models will be used to determine whether remote 6MW and other covariates listed in Section 10 can be used to predict in clinic 6MW. Cross-validation will be used to evaluate performance.

Gaussian linear regression models will be used to assess the ability to predict 6MW from covariates listed in Section 10.1 and previous 6MW. Cross-validation will be used to assess the performance.

For estimation of mediation, mixed effects regression analysis will be performed with random slope and intercept for each participant and unstructured covariance matrix. The direct and indirect effects of the intervention will be examined. Indirect effects analysis can provide important information about underlying mechanisms (e.g., treatments could achieve the same outcome via different mechanisms). Particular attention will be paid to the potential mediating/moderating effects of pain and self-efficacy. For indirect effects analyses, sensitivity analyses will be conducted to examine the robustness of effects under different assumptions regarding missing data. Gender-specific effects of the intervention will also be investigated.

A limited dataset (including first name, email address, zip code and study ID number) for the COVID-19 questionnaires may be shared and analyzed with IRB_00140849 ‘Exemption Umbrella Protocol- HCI projects. This will facilitate a larger review of the impact of COVID-19 on all patient populations listed in the umbrella protocol.

11 REGISTRATION GUIDELINES

Patients must meet all of the eligibility requirements listed in Section 5 prior to registration.

Patients must not have any study procedures or begin protocol treatment prior to registration.

Randomization to the Intervention or Control Arm will be done at the time of enrollment by the enrolling coordinator using OnCore (the Clinical Trials Office’s electronic clinical research management system).

12 DATA SUBMISSION SCHEDULE

The Case Report Forms (CRFs) for this study are a set of electronic forms for each patient that provides a record of the data generated according to the protocol. CRFs should be created prior to the study being initiated and updated (if applicable) when amendments to the protocol are IRB approved. Data capture should be restricted to endpoints and relevant patient information required for planned manuscripts. These forms will be completed on an on-going basis during the study. The medical records will be source of verification of the data. During the study, the CRFs will be monitored for completeness, accuracy, legibility and attention to detail by a member of the Research Compliance Office. The CRFs will be completed by the Investigator or a member of the study team as listed on the Delegation of Duties Log. The data will be reviewed no less than annually by the Data and Safety Monitoring Committee. The Investigator will allow the Data and Safety Monitoring Committee or Research Compliance Office personnel access to the patient source documents, clinical supplies dispensing and storage area, and study documentation for the above-mentioned purpose. The Investigator further agrees to assist the site visitors in their activities.

13 SPECIAL INSTRUCTIONS

13.1 Correlative Studies – *Optional Participation*

13.1.1 Blood

Correlative blood samples will be taken at the pre-operative visit as well as at the 2 months post-surgery visit. A blood questionnaire will be completed during the time of blood collection, unless the participant declines the blood draw. Staff may ask the questions from the blood questionnaire remotely. The blood will not be collected if the Biospecimen and Molecular Pathology Shared Resource at the Huntsman Cancer Institute is closed at the time of collection.

One 10mL red top tube and two 10mL EDTA tube will be collected at each visit. Serum, plasma and buffy coat will be stored for future analysis.

13.1.2 Saliva

Patients will be asked to collect a saliva sample at 6 months follow-up. A saliva questionnaire will also be completed during the time of saliva collection, unless the participant declines providing the saliva. Staff may ask the questions from the saliva questionnaire remotely. The saliva will not be collected if the Biospecimen and Molecular Pathology Shared Resource at the Huntsman Cancer Institute is closed at the time of collection. Saliva samples will not be completed during the COVID-19 outbreak to ensure study personnel safety. The collection of saliva samples may resume if the study team decides the risk to study personnel safety is minimized.

13.1.3 Sample Sharing

Samples may be shared with internal studies including but not limited to the Total Cancer Study (IRB #89989). The samples shared with Total Cancer Care will be shared only if the participant has also signed the Total Cancer Care consent. Studies will need to submit a request as part of the standard Biospecimen Request Form” in writing to study principal investigators and specify the sample type, amount, purpose, and participant identifiers (if applicable) they are requesting. The principal investigators will either approve or disapprove of the request. All studies requesting samples will be outlined in the protocol.

14 ETHICAL AND REGULATORY CONSIDERATIONS

14.1 Informed Consent

Informed consent will be obtained from all research participants prior to performing any study procedures using the most recent IRB approved version.

14.2 Institutional Review

This study will be approved by the Institutional Review Board of University of Utah.

14.3 Data and Safety Monitoring Plan

A Data and Safety Monitoring Committee (DSMC) is established at Huntsman Cancer Institute (HCI) and approved by the NCI to assure the well-being of patients enrolled in Investigator Initiated Trials that do not have an outside monitoring review. Roles and responsibilities of the DSMC are set forth in the NCI approved plan. The activities of this committee include a quarterly review of adverse events including SAEs, important medical events, and significant revisions or amendments to the protocol. If the DSMC and/or the PI have concerns about unexpected safety issues, the study will be stopped and will not be resumed until the issues are resolved. The DSMC also reviews and approves audit reports generated by the Research Compliance Office.

14.4 Adverse Events / Serious Adverse Events

An adverse event is the appearance or worsening of any undesirable sign, symptom, or medical condition occurring after starting the study drug even if the event is not considered to be related to study drug. For the purposes of this study, the terms toxicity and adverse event are used interchangeably. Medical conditions/diseases present before starting study drug are only considered adverse events if they worsen after starting the PEP regimen. Abnormal test results constitute adverse events only if they induce clinical signs or symptoms, are considered clinically significant, or require therapy.

For this low-risk study, information about a subset of adverse events of interest will be collected, recorded and followed as appropriate. This subset includes **any injuries, events, and conditions with a causal relation to the PEP intervention and require medical attention.**

Study-Specific AE Reporting plan

There is no protocol-directed administration of systemic therapy in this nonpharmacologic study; patients may be taking standard of care anti-cancer therapy prescribed by their treating oncologist. This study poses no greater than minimal risk to the human subjects. Therefore, the study-specific AE reporting plan detailed below will be followed. Any AEs with a *causal* relation to the research will be reported as described below. Timing of reporting is based on the IRB standard reporting guidelines. The PI will determine the attribution/relatedness of each AE.

<i>Reportable Events</i>	<i>Timing of Report to IRB</i>
Unanticipated problem involving risks to subjects or others	Serious-within 7 days Non-Serious-with scheduled continuation
Any grade 3 or 4 physical, social, or psychological adverse events that are related or possibly related to participation in this research study (e.g., AE related to questionnaire completion, physical assessments) regardless of expectedness	Within 7 days
Death while on study related or possibly related to participation in this study	Within 7 days
Death while on study unrelated to participation in this study	With SCR
<i>Non-Reportable Events</i> <ul style="list-style-type: none"> • Expected grade 1 or 2 side effects of exercise/activity, including typical muscle soreness associated with activity • Expected side effects of cancer therapy • Hospitalizations related to disease progression or scheduled surgeries • Any physical, social, or psychological harm grade 1 or 2 • Other serious events unrelated to participation in the research 	

Subjects will receive a systemic treatment regimen for their cancer during study participation. Since such routine interventions and treatment may influence the study results, information regarding the concomitant medications and toxicities experienced by each subject will be collected using the validated questionnaires but not reported to the IRB, as described above.

The occurrence of adverse events should be sought by non-directive questioning of the patient at each visit or phone contact during the study. Adverse events also may be detected when they are volunteered by the patient during or between visits or through physical examination or other assessments. As far as possible, each adverse event should be evaluated to determine:

1. Its severity grade based on CTCAE v.4 (grade 1-5).
2. Its relationship to the PEP intervention (definite, probable, possible, unlikely, not related).
3. Its duration (start and end dates or if continuing at final exam).
4. Action taken (no action taken; PEP intervention adjusted, temporarily interrupted, permanently discontinued due to this adverse event; concomitant medication taken; non-drug therapy given; hospitalization/prolonged hospitalization).
5. Whether it constitutes an SAE.

All adverse events will be treated appropriately. Such treatment may include changes in the intervention (as described in Figure 2). Once an adverse event is detected, it should be followed until its resolution, and assessment should be made at each visit (or more frequently, if necessary) of any changes in severity, the suspected relationship to the PEP regimen, the interventions required to treat it, and the outcome.

Study-Specific AE Reporting plan

There is no protocol-directed administration of systemic therapy in this nonpharmacologic study; patients may be taking standard of care anti-cancer therapy prescribed by their treating oncologist. This study poses no greater than minimal risk to the human subjects. Therefore, the study-specific AE reporting plan detailed below will be followed. Any AEs with a *causal* relation to the research will be reported as described below. Timing of reporting is based on the IRB standard reporting guidelines. The PI will determine the attribution/relatedness of each AE.

<i>Reportable Events</i>	<i>Timing of Report to IRB</i>
---------------------------------	---------------------------------------

Unanticipated problem involving risks to subjects or others	Serious-within 7 days
	Non-Serious-with scheduled continuation
Any grade 3 or 4 physical, social, or psychological adverse events that are related or possibly related to participation in this research study (e.g., AE related to questionnaire completion, physical assessments) regardless of expectedness	Within 7 days
Death while on study related or possibly related to participation in this study	Within 7 days
Death while on study unrelated to participation in this study	With SCR
<p style="text-align: center;"><i>Non-Reportable Events</i></p> <ul style="list-style-type: none"> <input type="checkbox"/> Expected grade 1 or 2 side effects of exercise/activity, including typical muscle soreness associated with activity <input type="checkbox"/> Expected side effects of cancer therapy <input type="checkbox"/> Hospitalizations related to disease progression or scheduled surgeries <input type="checkbox"/> Any physical, social, or psychological harm grade 1 or 2 <input type="checkbox"/> Other serious events unrelated to participation in the research 	

Subjects will receive a systemic treatment regimen for their cancer during study participation. Since such routine interventions and treatment may influence the study results, information regarding the concomitant medications and toxicities experienced by each subject will be collected using the validated questionnaires but not reported to the IRB, as described above.

14.5 SAE Reporting Requirements

SAEs must be reported to the DSMC as well as the IRB and the FDA (when applicable) according to the requirements described below:

The Investigator (or a properly delegated study team member) must complete a MedWatch 3500A form and submit it to the Research Compliance Office

(compliance@hci.utah.edu) as soon as possible, but no later than 10 business days of first knowledge or notification of the event (5 business days for fatal or life threatening event).

14.5.1 DSMC Notifications

Upon receipt of the MedWatch 3500A, an HCI Research Compliance Officer will process and submit the form to the proper DSMC member as necessary for this study.

The RCO will summarize and present all reported SAEs according to the Data and Safety Monitoring Plan at the quarterly DSMC meeting.

14.5.2 IRB Notifications

Events meeting the University of Utah IRB reporting requirements (described at (<https://irb.utah.edu>)) will be submitted by the Investigator (or a properly delegated study team member) through the IRB's electronic reporting system (ERICA) within 10 working days.

14.5.3 FDA Notifications

Adverse events occurring during the course of a clinical study that meet the following criteria will be promptly reported to the FDA:

- Serious
- Unexpected
- Definitely, probably, or possibly related to the intervention

Fatal or life-threatening events that meet the criteria above will be reported within 7 calendar days after first knowledge of the event by the investigator; followed by as complete a report as possible within 8 additional calendar days.

All other events that meet the criteria above will be reported within 15 calendar days after first knowledge of the event by the investigator.

Prior to submission to the FDA, the RCO will review the MedWatch report for completeness, accuracy and applicability to the regulatory reporting requirements. The MedWatch report will then be submitted to the FDA through the voluntary reporting method by the Regulatory Coordinator.

14.6 Protocol Amendments

Any amendments or administrative changes in the research protocol during the period, for which the IRB approval has already been given, will not be initiated without submission of an amendment for IRB review and approval.

These requirements for approval will in no way prevent any immediate action from being taken by the investigator in the interests of preserving the safety of all patients included in the trial.

14.7 Protocol Deviations

A protocol deviation (or violation) is any departure from the defined procedures and treatment plans as outlined in the protocol version submitted and previously approved

by the IRB. Protocol deviations have the potential to place participants at risk and can also undermine the scientific integrity of the study thus jeopardizing the justification for the research. Protocol deviations are unplanned and unintentional events.

Because some protocol deviations pose no conceivable threat to participant safety or scientific integrity, reporting is left to the discretion of the PI within the context of the guidelines below. The IRB requires the **prompt reporting** of protocol deviations which are:

- Exceptions to eligibility criteria.
- Intended to eliminate apparent immediate hazard to a research participant, or
- Harmful (caused harm to participants or others, or place them at increased risk of harm - including physical, psychological, economic, or social harm), or
- Possible serious or continued noncompliance

14.8 FDA Annual Reporting

This study is IND exempt therefore there are no annual reporting requirements to the FDA.

14.9 Clinical Trials Data Bank

The study will be registered on <http://clinicaltrials.gov> and the NCI CTRP (Clinical Trials Reporting Program) by the Clinical Trials Office.

APPENDIX 1 - AM-PAC Basic Mobility Outpatient Form and Conversion Table

Precision Exercise Prescription PEP-Study

Boston University AM-PAC™

Generic Basic Mobility Outpatient Short Form

Please check the box that reflects your best answer to each question.

How much difficulty do you currently have ...	Unable	A Lot	A Little	None
1. Bending over from a standing position to pick up a piece of clothing from the floor without holding onto anything?	1	2	3	4
2. Standing up from a low, soft couch?	1	2	3	4
3. Taking a 1-mile brisk walk, without stopping to rest?	1	2	3	4
4. Running for 5 minutes on even surfaces?	1	2	3	4
5. Walking several blocks?	1	2	3	4
6. Walking up and down steep unpaved inclines (e.g., steep gravel driveway)?	1	2	3	4
7. Running a short distance, such as to catch a bus?	1	2	3	4
8. Carrying something in both arms while climbing a flight of stairs (e.g., laundry)?	1	2	3	4
9. Going up and down a flight of stairs outside, without using a handrail	1	2	3	4
10. Making sharp turns when running fast?	1	2	3	4
11. Taking part in strenuous activities (e.g., running 3 miles, swimming half mile, etc.)	1	2	3	4
12. Standing up from an armless straight chair (e.g., dining room chair)?	1	2	3	4
13. Walking on an uneven surface (e.g., grass, dirt road or sidewalk, brick walkways, sidewalks with curb and driveways cuts)?	1	2	3	4
14. Walking around one floor of their home, taking into consideration thresholds, doors, furniture, and a variety of floor coverings?	1	2	3	4
15. Doing light housework (e.g., dusting, minor sweeping)?	1	2	3	4
16. Moving up in bed (e.g., reposition self)?	1	2	3	4
17. Getting into and out of a car/taxi (sedan)?	1	2	3	4
18. Cleaning up spills on the floor with a mop?	1	2	3	4

*Use this form to convert AM-PAC Generic Basic Mobility Outpatient Raw Scores.

AM-PAC Generic Outpatient Basic Mobility Short Form Scoring Example

1. Add the number values associated with the response to each item. For example, items totals yield a Raw Score of 55.
2. Match the raw score to the t-Scale scores (t-Scale score = 63.31, SE = 1.72).
3. Find the associated CMS % (CMS % = 33.39%).
4. Locate the correct CMS Functional Modifier Code, or 'G Code' (G code = CJ)

NOTE: Each AM-PAC Short Form has a separate conversion table. Make sure that you use the correct conversion table.

Protocol name: Precision Exercise Prescription Randomized Clinical Trial

Version Date: 24NOV2021

Previous Version: 16JUN2021

Principal Investigator: Paul LaStayo, PhD, PT

APPENDIX 2 - AM-PAC Basic Mobility Staging and Expected Performance

Stage 5: 84 – 104.9 Strenuous Recreation/Sports

Your score suggests a high level of independence in moving about both at home and in the community. You may be able to participate in most physical activities without much difficulty.

Stage 4: 66 – 83 Moving Around Outdoors

Your score suggests that you are able to walk inside your home and other buildings without any difficulty. You may be able to move about outdoors without any limitations. You should be able to bend over and pick up things without much difficulty. Activities that might be difficult to manage without assistance include climbing a full flight of stairs, bending, kneeling or stooping. Vigorous activities such as playing sports or walking several miles may be very difficult to complete.

Stage 3: 52 – 65 Moving Around Indoors

Your score suggests that you may be able to move about on the ground floor of your home where you are familiar with the environment. Activities that might be difficult to manage without assistance include sitting and standing from a low chair, climbing stairs, bending, kneeling or stooping. You may have some difficulty moving about outdoors and in the community.

Stage 2: 34 – 51 Limited Mobility Indoors

Your score suggests significant difficulty in moving about independently and the need for assistance. You may be able to move about in a small area of your home that has been adapted to eliminate safety hazards. You may have difficulty moving from a sitting to standing position, climbing stairs and you may have a great deal of difficulty moving about outdoors and in the community.

Stage 1: -11.95 – 33 Limited Movement

Your score suggests you may have a lot of difficulty or are unable to get out of your bed, to stand for several minutes and/or to walk short distances. You might have some difficulty completing the most basic mobility tasks including repositioning yourself in bed.
